As I have said, the main object of treatment is the correction of the "twisting in"—in other words, of the longitudinal curve as it affects the fore-part of the foot. If this *be fully corrected, the foot will be a satisfactory one;* but, on the other hand, if it be allowed to persist, the result will be bad, no matter what else is done. The reason for this is a principle to which I have already referred—that it is impossible to turn the fore-part of the foot outwards without correcting the varus into valgus, and that as this turning out proceeds further the foot as a whole swings into calcaneus. Consequently, by the time the fore-foot is turned fully outwards, the only element of the deformity left is the bending inward of the heel,

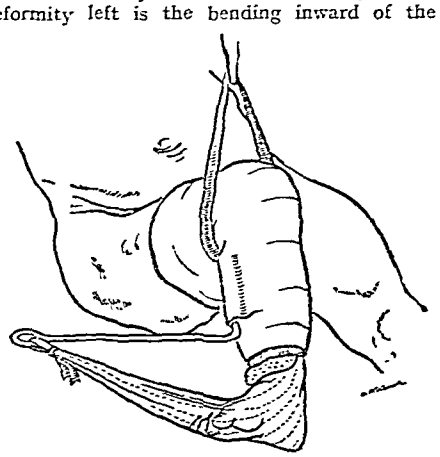

FIG. 4.—The "stocking splint" for correcting talipes.

which, *by itself*, is of negligible effect on appearance and function. It is fortunate that this should be so, as it is extraordinarily difficult to attack the heel directly. The main ways on which we rely for improving its position are, first, by leverage upon it from the fore-foot across the fulcrum of the ankle-joint, and secondly, by means of the free action upon it of the calf muscles, after the varus has been corrected.

I suggest that if the condition be assumed to be due to long-continued gentle moulding, the same sort of force may be the best means of correcting it. I do not think that anyone will deny the possibility of producing a deformity indistinguishable from congenital talipes, displacement of the astragalo-scaphoid joint and all, by pressure of this type applied in the early months of life, provided that it was as constant and ruthless as that which used to be undergone by high-born Chinese girls. A series of cases which I once treated by means of what might be called a "stocking splint" were interesting as to the possibilities of pressure of this kind. The splint (Fig. 4) consisted of a right-angled plaster over the knee,

holding a tube of stockinet round the leg. The lower end of this tube was attached at a slight constant tension to the end of an iron set in the plaster ; both the position of the iron and the pull of the fabric being continually adjusted. I do not recommend this method for general use, but it was possible by means of it to get a surprisingly rapid and complete over-correction of the type shown in Fig. 5.

Fig. 5.—Over-correction of talipes obtained by means of the stocking splint.

I am not, of course, maintaining that reduction of the original deformity can be attained without force ; many cases will tax all the strength of our fingers and any skill we may have with the Thomas wrench. But the disadvantages of violence must never be forgotten. Bone has peculiar reactions. If it is forcibly crushed and then left at rest, it tends to build itself up to its original structure and to even greater rigidity than before ; but if it is subjected to continual gentle compression, it melts before it and rebuilds itself in accommodation to the new stresses.

Another disadvantage of wrenching, and to a much greater degree of tenotomies, is that exasperating reaction by which the body, when we have separated two points by dividing the structures between them, fills up the gap with blood, turns this into scar tissue, and leaves it to contract with its familiar force and persistency. The result not seldom is that some time after the operation the bony points separated are in the same relation as before, except that instead of being connected by tissue of normal elasticity, they are indissolubly united by adherent and resentful scar tissue.

Apart from the rigidity thus produced, there is the bad effect of interference with the action of muscles upon their points of insertion. Consider, for instance, the characteristic marked atrophy of the calf muscles and the heel upon which they act. These two structures depend for their development into anything approaching the normal size upon mutual stimulation ; so that to deprive them of this by early division of the tendo Achillis is as disastrous as it is common.

It is not, however, in the attainment of over-correction that failure usually occurs. The trouble comes in maintaining the advantage gained, with, as a penalty for non-success, the repeated recourse to violent methods to restore the lost ground. For the reasons given, the best treatment will use as little violence as possible, striving for a method of restraint that will not only keep the feet in the best position possible, but will tend continuously to correct this position still further. In attempting this it must always be remembered that all the forces to which the foot is exposed, quite apart from the action of the unbalanced muscles and the automatic effect of walking, are hostile. Long clothes, bed-clothes, the position natural to every child of sitting upon the folded feet, all work to turn the toes inwards and downwards. In addition, the natural reaction of the young to any splint is to endeavour to wriggle out of it, and the instinctive way of extricating the foot from any grip is to turn it into equino-varus to minimize the projection of the fore-foot before pulling away. This means that as a general rule, until cure is complete, any time that is not spent either in effective restraint or in using the foot in the correct position is doing harm.

Methods of Treatment

If the main aim of restraining the foot is to maintain an outward bending of the fore-part, and if it be granted that in order to turn it outwards it is necessary to have some purchase from which to work, the various splinting methods can be grouped according to the anchorage they employ.

1. Tin shoes and external malleable splints.—For what it is worth the anchorage in these is their friction against the skin of the leg, but a study of the position of the foot of a vigorous baby some time after they have been applied does not lead to a very high opinion of their efficiency.

2. Sticking-plaster bands, which pull from a grip on the skin of the leg.—These have a better purchase than that of the first group, but this is obviously very weak mechanically, and apt to cause trouble with the skin. Also if the baby is watched in its mother's arms, it will be seen that they do not stop rotation inwards of the foot as a whole beyond the sagittal plane.

3. The use of the femur, held at right angles to the tibia, either by splints or by plaster, for a purchase.—These methods have in different degrees the grave fault of immobilizing the muscles of the leg, and also produce genu valgum by stretching the internal lateral ligament of the knee-joint.

4. The use of the pelvis as a fixed point from which to turn out the feet by means of walking irons.—This has obvious disadvantages, and is very seldom used now.

5. The method, which I believe to be original, of using one foot as a purchase for turning out the other by means of a " hobble splint."

The Hobble Splint

The principle on which this splint depends is, briefly, that if the two feet are fixed in relation to each other, they are also fixed in relation to the median plane of the body in general. Like other statements I have made, this statement is very difficult to prove shortly in the abstract, and yet it needs only the experiment of trying to twist the hips without shifting the position of the feet on the floor to demonstrate its truth. It will be found that " pivoting " is both uncomfortable and extremely limited.

The splint is made as a pair of foot-pieces connected together by the heels, the connexion forming a base from which the fore-parts of the feet can be " twisted out " to any desired angle to the sagittal plane of the body. The foot-pieces are extremely simple, being cut out on the flat in an L shape, with one limb corresponding to the sole of the foot in the position into which it is intended to mould it, and the other bent up at right angles to the heel end of this, so as to fit along the outer side of the leg. The upper end of the leg-piece should be slightly bent outwards to avoid digging into the skin, and will be found far better in this position than in the more usual one at the back of the leg.

These being the foot-pieces, it only remains to arrange them on their base in the correct position, which varies with every case. If there is a normal foot it should of course be inclined at the normal angle of about 20 degrees to the sagittal plane, and the correction to be aimed at in a talipes foot is to get it turned as far beyond this outwards as it was originally set beyond it inwards. In regard to this it may be remarked that one of the arguments in favour of the compression theory of causation is that though in double cases the deformity is always of the same order on both sides, it is never exactly equal ; the presumption being that the foot that is on the outer side in the cross-legged position is the more deformed.

Consequently its side of the splint must be turned out more than the other by 10 degrees or so.

The splint should be cut out of some fairly stiff metal (14 gauge hard aluminium is very suitable), and till the designing of it becomes familiar it is best to make a stiff cardboard model first. The base should first be sketched, the heels being placed with about an inch between their inner borders, and with a broad strip connecting them. Then from the position of the heels each foot-piece is marked out at the correct angle to the base, and finally at right angles to this is drawn the part to be folded up along the legs (Figs. 6 and 7).

To apply the splints, each foot is bandaged in separately by a figure-of-eight bandage of coarse flannel, the meeting of the folds over the instep driving the heel down into position (Fig. 8).

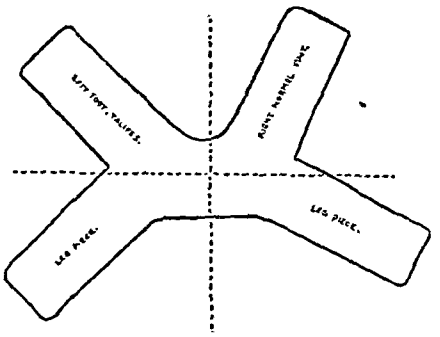

FIG. 6.—Hobble splint for moderate degree of left talipes, marked out on the flat.

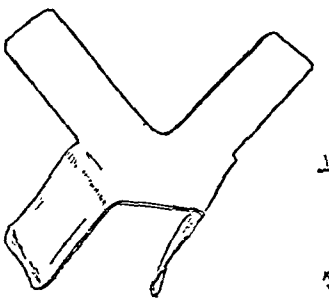

FIG. 7.—Hobble splint for double talipes, completed except for padding.

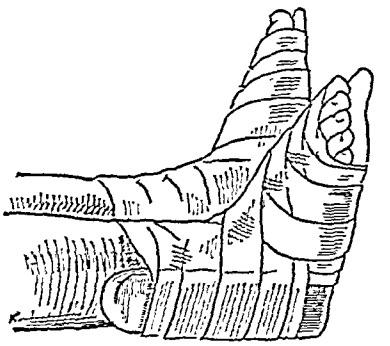

FIG. 8.—Hobble splint applied by figure-of-eight bandages.

I would claim the following advantages for this splint.

1. It is easily made and cheap.

2. One size of it has a very wide range of fitting, so that it does not need to be continually changed as the child grows.

3. The pressure on the foot is applied by soft material over wide areas, and not by hard surfaces to bony points. Consequently there is little tendency to chafing.

4. It is easily applied by an untrained mother once she has mastered the idea of the figure-of-eight bandage, which automatically pulls the foot into position.

5. It is almost impossible to wriggle out of it. It is interesting to see the powerlessness of the child when held in this way. The jiu-jitsu effect of preventing the preliminary inward turn in freeing the foot can only be appreciated by applying a splint of this type to oneself.

6. It really does maintain the outward bending of the foot gained by manipulation, with surprisingly good secondary effects on the equinus and varus.

7. The child can kick freely with the splint in position, so exercising the muscles of the calves and thighs. This is of the utmost importance in developing both these muscles and the bony points to which they are attached, more especially the heel.

In conclusion, I would say that I am fully conscious of the drastic simplifications which I have made of extremely complicated problems. I believe, however, that these simplifications are correct as far as they go. Their disproof lies in the production of cases in which the "twisting in" has been corrected, but in which crippling persists: for their proof I can only ask for a trial of the splint.

I have to thank Dr. C. A. Keogh for that help which only an illustrator who understands the argument can give.

BACTERIAL ENDOCARDITIS IN AN INFANT 13 DAYS OLD

BY

JOHN D'EWART, M.B.

MEDICAL SUPERINTENDENT, BOOTH HALL HOSPITAL, MANCHESTER

When Finkelstein[1] suggested in 1905 that the endocardium of the infant was possessed of definite immunity against infection, it is obvious that acute endocarditis in infants was considered to be impossible. Considerably later the opinion was definitely held that, if not non-existent, the condition was certainly very rare. In successive editions of Still's *Common Disorders and Diseases of Childhood* the view is reiterated that "under the age of 3 years it is extremely rare, and under the age of 2 years it is almost unknown." In Ashby and Roberts (1922) it is stated that "endocarditis occurs at all periods of life, it may even attack the foetus: it is met with only rarely under 4." It is stated in Griffith's *Diseases of Infants and Children* (first edition) that "the inflammation may occur in foetal life and thus be one of the causes of congenital cardiac abnormalities. It is uncommon in infancy." Griffith reports that Steffen observed five cases under 1 year, and that Sutiagin reported eleven in the first year, but he considers that such numbers are certainly unusual. Lees and Poynton report one case under 3½ years, and Poynton, in his recent address at the Invalid Children's Aid Association, gave as his impression that about 12 per cent. occur under the age of 5. Bass (Abt's *Pediatrics*, iv, 362) states:

"Acute endocarditis occurs during foetal life, as a rule, on the right side of the heart and in conjunction with developmental defects. Of the post-natal infections, one of the youngest cases is that reported by Czerny in an infant of 1 month suffering from septic endocarditis. Such a case, however, is very exceptional, since endocardial inflammation is rare in children under 2 years of age. In 1,000 post-mortem examinations Holt found no case of acute endocarditis in children under 3 years of age. Steffen (quoted by Lempp), in tabulating forty-five cases of endocarditis in children, found five in children under 1 year; von Dusch, in the same number of cases, reports five in children between the ages of 8 months and 5 years. Lempp reports seven definite cases from Finkelstein's clinic. All of these are in infants, and the mitral valve was shown by autopsy to have been involved in every case. Finkelstein reports fifteen cases of endocarditis in infants, and believes that even at this early age two-thirds of the cases are due to rheumatism, the other third being a manifestation of sepsis. After the second year, and thereafter as the age of the child increases, endocarditis becomes more frequent."

Czerny's case has not been verified.

Later observations tend to show that infantile bacterial endocarditis is not quite so rare as has been considered.

Three cases were reported last year, and I here present another case, the youngest yet on record, the patient being only 13 days old at death.

History of the Case

A male baby, born on September 19th, 1930, was admitted on October 1st on account of haemoptysis He was a full time baby and only weighed 2 950 grams, and had been fed on Nestle's milk, supplementary to the breast When admitted he was slightly cyanosed, and twenty hours after admission had a profuse nasal haemorrhage of bright red and frothy blood and died almost immediately (October 2nd)

The post mortem findings were as follows The urachus contained a little pus just within the umbilicus The trachea and bronchi contained frothy blood, the lining walls being normal The lower lobes of both lungs showed numerous peripheral areas of consolidation, dark red, almost black, well defined, and raised above the surface of the aerated lung *The upper lobes were aerated, but had a few discrete areas*—similar to those found in the lower lobes—much smaller and more clearly defined These were undoubtedly small infarctions, but the actual source of the terminal haemorrhage was not discovered An area of endocarditis was discovered on the posterior wall of the right ventricle, about 1/4 inch proximal to the pulmonary valve This area, 3/4 inch by 1/8 inch, consisted of dark coloured fibrinous exudate, which stripped easily from the endocardium, leaving a roughened surface The heart valves were normal

The microscopical examination of the fibrinous material loosely attached to the endocardium below the pulmonary valve had the appearance of acellular decolorized clot deposited from the moving blood stream In sections stained for bacteria staphylococci were present in large numbers There was no microscopical evidence of disease of the heart muscles

Conclusions

The appearances in the upper lobes of the lung were due to pulmonary infarction, and in the lower lobes to insufflations of blood The primary focus was the septic condition of the cord, followed by a secondary infective (staphylococcal) endocarditis, which gave rise to multiple pulmonary infarction

RAPID LABORATORY TEST FOR PREGNANCY

BY

GLADYS H DODDS, M D, D P H

ASSISTANT IN THE OBSTETRIC UNIT, UNIVERSITY COLLEGE HOSPITAL

During the last few years, and particularly since the introduction into general use of the Zondek-Aschheim test for pregnancy, numerous investigators have attempted to find a test which is as reliable and which would give more rapid results The great advantage of rapid diagnosis in cases of ectopic gestation or fibroids and pregnancy is obvious

Zondek and Aschheim[1] showed that the urine of pregnant women contained a substance which produced certain characteristic changes—namely, corpora haemorrhagica and corpora lutea—in the ovaries of the immature female mouse They also showed that, with few exceptions, this ovary stimulating substance was peculiar to the urine of pregnancy Friedman,[2] in 1929, appears to have been the first to have studied the mechanism of ovulation of the rabbit by injection of urine of pregnant women He showed the advantage of using the rabbit instead of the mouse to test for substances which produce ovulation In the rabbit, ovulation[3] does not occur until the age of 5 months in the summer and 6 to 8 months in the winter, ovulation is dependent on copulation, and following copulation ovulation occurs in eight to ten hours Ovulation is easily recognized by inspection of the ovaries, either fresh corpora lutea or projecting corpora haemorrhagica can be seen on the surface In a series of twenty-two rabbits in which Friedman had injected 5 c cm of urine intravenously, positive results were obtained from the urine of eighteen pregnant, and negative results from the urine of fourteen non-pregnant, women Nine of the positive results were noted twenty-four hours after the injection Friedman suggested that the test might be useful in the diagnosis of pregnancy

Adele Brouha,[4] in the early part of this year, described a similar test for pregnancy She used virgin rabbits weighing about 1 kilogram, and, with a single intravenous injection of urine, obtained results in fifteen to twenty-four hours Brouha[5] carried out the test in nearly two hundred cases in which the diagnosis was in doubt, and in each case the laboratory findings agreed with the clinical

Reinhart and Scott,[6] Schneider,[7] Magath and Randall[8] and Friedman and Lapham[9] have used a similar method for the diagnosis of pregnancy. Their techniques varied but their results have been as good as those of the Zondek-Aschheim test Reinhart and Scott used adult female non-pregnant rabbits weighing not less than 4 lb, they gave a single injection, and obtained results in twenty-four hours, in a series of fifty cases they had only one error. Schneider used female rabbits, aged 12 to 14 weeks, he gave a single injection, and obtained results in twelve to twenty-four hours, in a series of one hundred cases there were two errors, and in these two the technique was faulty. Schneider recommends the use of two rabbits in cases of urgency, as in some cases a result may be obtained in twelve hours, which may be confirmed later in another twelve hours Magath and Randall used female rabbits over 2½ months old, they gave a single injection, and obtained results in thirty hours, in a series of eighty-five cases they had two errors Friedman and Lapham used unmated mature female rabbits The urine was injected thrice daily for two days in 4 c cm doses Forty-eight hours after the first injection the rabbit was killed Before they adopted this routine Friedman and Lapham used the single injection, with post-mortem eighteen hours later, but they found that it was not entirely reliable, although in case of urgency it could be used if too much reliance was not placed on negative results.

Technique and Results

The rapidity and reliability of the test, according to these observers, suggested its use to us, and we consider that the results in a small series of fifty-three cases investigated at University College Hospital worthy of record

The technique used in the first twenty cases was that of Adèle Brouha A single intravenous injection of 8 to 12 c cm of urine was given to virgin rabbits weighing about 1 kilogram, and a post-mortem was done fifteen to twenty-four hours later Urine from seventeen pregnant and three non-pregnant women was investigated;

there were six errors (30 per cent.), all in the pregnant group. The period of pregnancy in the cases investigated was from six to fourteen weeks, a period during which the test is most useful. There were two cases of hydatidiform mole, and each gave a positive result. The technique adopted in the remaining thirty-three cases was as follows. Virgin rabbits, aged 12 to 20 weeks, were used, and two injections of 6 c.cm. were given intravenously for two days. Forty-eight hours after the first

FIG. 1.—Ovary of 12-weeks-old rabbit, which had been injected with urine from a non-pregnant woman. (×1½.)

FIG. 2.—Ovary of 12-weeks-old rabbit, which had been injected with urine from a pregnant woman. Note projecting corpora haemorrhagica. (×1½.)

injection the ovaries were inspected. Of the thirty-three cases twenty-eight were pregnant and five not pregnant, and in all cases the diagnosis was correct.

COMMENTARY

In the first series of twenty cases there was an error of 30 per cent. The failure in this series is, I believe, due to the fact that the rabbits were too young, as Snyder and Wislochi[10] have shown that ovulation cannot be produced, even with concentrated urine, in rabbits aged less than 12 weeks. The rabbits used in this series were aged 10 to 12 weeks. In the second series the results are as good as those of the Zondek-Aschheim test.

An advantage of this test is the fact that rabbits are used; these animals are readily obtained, while the five female mice, of specific age and weight, required for the Zondek-Aschheim test are not always available. Provided that the rabbit is not less than 12 weeks old, the age and weight are of no consequence. It is essential to be certain that ovulation has not taken place recently before the test is done, and that the rabbits are not pregnant. To ensure this, rabbits should be kept isolated for twenty days. It is also recommended that each rabbit should be isolated to avoid the possibility of pseudo-ovulation. Mortality among the rabbits has been a negligible factor. Morning specimens of urine were examined. Sterile precautions in injection of urine are not necessary.

CONCLUSION

The test is simple, rapid, and as reliable as the Zondek-Aschheim test.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

PRIMARY LARYNGEAL DIPHTHERIA

Respiratory obstruction in a child may not be considered to be diphtheria in the absence of a membrane on the pharynx, and this may lead to the mere performance of a tracheotomy without the administration of diphtheria antitoxin. On one occasion I saw a child *in extremis* with respiratory obstruction on whom no diagnosis had been made, but on which a tracheotomy had been performed. The child died, and I have always wondered whether that child had laryngeal diphtheria. I think the following case is worth reporting, because I was able to see a membrane on the vocal cord on making a direct laryngeal examination, though no sign of a membrane was present in the pharynx.

An infant, aged 5½, was admitted to the hospital at 7 p.m. because of difficult respiration. The pharynx was normal in appearance. The house-surgeon considered that a tracheotomy was not then necessary, but informed me of the child's admission. At 10 p.m. I saw the child. At 9.45 a catheter had been inserted into the nostril and oxygen was administered continuously; epigastric dipping and retraction of the intercostal spaces were present; the child was cyanosed and restless.

I injected novocain and made an incision. The haemorrhage was profuse, the child's pupils dilated fully, and breathing ceased. So I plunged the knife into the trachea and inserted a Jackson's tracheotomy tube. The child would not breathe and the pupils were still dilated, so I placed the tube from the CO_2 cylinder in the tracheotomy tube and did artificial respiration. After some minutes breathing began. I then passed a Flagg's laryngoscope, and found the centre of the right vocal cord covered with a white membrane; the house-surgeon (Dr. E. D. F. Forster) injected 26,000 units of anti-diphtheria serum, and transferred the child to the fever hospital.

In the fever hospital the medical officer of health for Darlington, Dr. G. A. Dawson, took charge of the child on the morning of July 12th, and he kindly sent me the following report:

On examination the temperature was 99.6°, pulse 142, tonsils much enlarged and injected, no membrane or deposit visible. At 4 p.m. on July 12th he was highly excited through respiratory distress; the tube was withdrawn, and a small piece of diphtheria membrane the size of a sixpence was removed by forceps, and 40,000 units of anti-diphtheritic serum was given intravenously. . . . On July 14th at 7 a.m., after a fit of coughing, cyanosis became very marked, due to tracheal obstruction. Dr. Dawson was summoned, and removed the tube and introduced dilators moistened with a solution of 15 per cent. sodium carbonate. A tough membranous tracheal cast 3½ in. long by 1/2 in. wide was removed by the use of forceps, giving immediate relief. The child made an uninterrupted recovery, and was discharged from hospital on August 20th. Dr. Dawson adds a note saying, "Every case of laryngeal obstruction of catarrhal origin should, in my opinion, be looked upon and treated as diphtheria, by the early intravenous administration of large doses of anti-diphtheritic serum."

Had the true nature of the condition been recognized antitoxin would have been given before the child was admitted to hospital, but, as it was, the condition was not recognized until three hours after admission. In tracheobronchial diphtheria the best treatment is a low tracheotomy, with repeated aspiration through a catheter attached to a suction machine such as all laryngologists now have. Such a machine should be kept in the patient's room, and should be used by the nurse. Bronchoscopy via the tracheal wound can easily be performed if necessary.

After doing a tracheotomy it is unwise to flood the lungs with oxygen or with air, and so the small hand CO_2 cylinder, as now used by all anaesthetists, ought to be always present, and immediately on opening the trachea CO_2 ought to be administered. Thus modern methods of endoscopy constitute a scientific diagnostic approach; but, in the absence of endoscopy, it is safe to treat a case of acute respiratory obstruction due to an unknown cause as diphtheria, and so administer the antitoxin early.

Harrogate. F.R.C.S.Ed.

AN UNUSUAL METHOD OF REMOVING A FOREIGN BODY

On August 4th a man aged 46 was referred to me by his doctor with the following history. His wife died some years ago, and recently he had been much disturbed by nocturnal emissions. In an effort to restrain testicular activity he had, on July 30th, pulled his scrotum and testes through a case-hardened steel ring, which he could neither slide off nor cut through. Before seeking medical advice he had tried to divide it with a hammer and cold-chisel, but had been unable to make any impression on the metal. On examination, the base of the scrotum was found to be constricted by a metal ring of an internal diameter of 1.15 inches; its external diameter was 1.9 inches, and its depth 0.7 inch. The ring fitted sufficiently loosely to allow it to be turned, and a probe could be passed beneath it. The skin had been abraded by its sharp edges, and the whole scrotum was oedematous.

The man was admitted to hospital, and cold compresses were applied in an effort to reduce the oedema and permit of the withdrawal of the ring. As this manœuvre did not appear likely to succeed, preparations were made to cut through the hardened steel. The hospital engineer was called in and advised that the only thing likely to succeed was a carborundum wheel driven by an electric motor. He procured the apparatus and asked me to make arrangements for protecting the scrotum from the heat by drawing a strip of sheet asbestos through between the ring and the skin and by playing a constant stream of water over the surface that was being cut. He also warned me that the apparatus, when working, produced a stream of sparks which would necessitate protection both for the patient and for the operator's eyes.

The patient was anaesthetized and a further effort was made to squeeze the oedematous fluid from the scrotum and to slide off the ring. My efforts to do this having failed, I asked the engineer to take charge, another surgeon and myself assisting him. The sheet asbestos was duly introduced, the ring was firmly grasped in a screw wrench, and mackintoshes were arranged to catch the sparks. A stream of water was played over the line of section, and the instrument was brought into play. The heat generated was surprising, and the stream of sparks was projected for fully six feet. Approximately fifty minutes was taken to cut through the ring in two places so that the halves could be separated and removed. Very little damage was done to the scrotum.

Although this was the engineer's first excursion into the realms of surgery, it was apparent that he had mastered the art of cutting hardened steel under awkward conditions. The fact that he was able to do so without producing trauma speaks very highly for his manipulative skill. The patient was sufficiently recovered to leave hospital less than twenty-four hours after the operation. The ring has been presented to the museum of the Royal College of Surgeons.

CLINICAL AND SCIENTIFIC PROCEEDINGS

SOUTH INDIAN BRANCH

Etiology and Treatment of Sprue

At a meeting of the South Indian Branch, with the president, Major-General C. A. Sprawson, I.M.S., in the chair, Dr. K. Narayanamoorthi, Research Fellow in Medicine at the University of Madras, read a paper on the cause, symptomatology, and treatment of sprue.

Dr. Narayanamoorthi said that a close and careful study of thirty-three cases of sprue treated at the School of Tropical Medicine, Calcutta, and of forty-five cases treated at the Government General Hospital, Madras, had been made. Etiology seemed to turn on the point that the infection was much more common in adults, both among the Europeans and the Indians; the disease affected the fairly well-to-do classes rather than the coolie classes. There was a history of some form of dysentery, amoebic or bacillary, but the patients were not addicted to alcohol or tobacco. Depressing circumstances, such as mental worry, fatigue, and insomnia seemed to precipitate the onset. Fairly often there were three phases in the course of the disease, from the bacteriological point of view, the first being a post-Flexner bacillary infection, the second the occurrence of streptococci on the tongue or in the stools, and sometimes in the urine, and the third a phase of infection by the *Monilia psilosis* (Ashfordii). The symptoms were different in the three phases. The serums of patients suffering from sprue were found to give a positive agglutination reaction with Flexner's bacillus to a titre 1 in 160. Streptococci (often haemolytic) and Monilia in a majority of cases had been isolated. The speaker was inclined to consider that the symptoms of sprue indicated a post-dysenteric phenomenon.

The onset of the disease was slow and insidious; untreated or improperly treated cases of chronic dysentery appeared to develop into the clinical condition of sprue. Loss of appetite, soreness of the tongue, progressive emaciation, extreme weakness, distension of the abdomen, diarrhoea, and varying degrees of anaemia—the severest resembling, and often indistinguishable from, a true Addisonian anaemia—had been observed. The disease on the whole was afebrile, but, of late, cases had been noted at Madras with pyrexia of a typhoid type. The serum of these patients gave a 1 in 100 positive reaction against *B. faecalis alkaligenes*, and a negative one to the typhoid and paratyphoid bacilli. *B. faecalis alkaligenes* had been isolated from stools in these cases. The pyrexia was thought to be of the nature of a septicaemia, as in the case of typhoid. The diagnosis of sprue in the above cases was based upon (1) the clinical symptoms; (2) *x*-ray examination after a bismuth meal; (3) a fractional test meal; (4) estimation of the total fat and fatty acids in stools; and (5) the bacteriological examination of stools and urine for non-lactose fermenters, streptococci, and Monilia. To gauge the prognosis a complete cytological examination of blood, the van den Bergh test, estimation of the organic and inorganic calcium content of the serum, and of the blood cholesterol had been undertaken. The van den Bergh test was found to give an indirect positive reaction of 1.5 to 6 units of bilirubin. Calcium deficiency had not been found in all these cases; the normal calcium in the Indian, from the speaker's figures, seemed to be below 8–10 mg.

A high protein diet, including milk, eggs, fruit, bananas, oranges, bael-fruit, sapotas, tomatoes, greens, onions, and radishes, was very effective in treatment. Autogenous vaccines prepared from the isolated organisms, liver

therapy, ventriculin (in those with liver failure), and autohaemic injections were also found to be very useful With insulin therapy a remarkable improvement in weight had been noted in our cases Dr Lucy Wills had stated that marmite had given excellent results as regards the anaemia, but, so far, the speaker was not in a position to give an opinion All the symptoms, with the exception of the anaemia, were controlled by the outlined treatment in a great majority of the cases The anaemia presented a blood picture of the pernicious type, it was found to persist, despite all methods used for bringing about haematopoiesis Tetany had not been noticed in these cases

Reports of Societies

THE LARYNGOSCOPE IN MEDICINE

At the annual general meeting of the Medical Society of London on October 12th, Mr HERBERT TILLEY was inducted into the chair, and proceeded to deliver his presidential address on the subject of "The laryngoscope in medicine"

Mr Tilley began by outlining the history of the instrument, and went on to speak of the value of the laryngeal mirror in clinical medicine, and some of the developments to which it had given rise He gave instances of some tentative work in this direction by the early laryngologists, and referred to a meeting of the Medical Society of London on December 15th, 1862, at which, following a paper read by Dr Gibb on "Illustrations of the practical applications of the laryngoscope," Dr Streeter mentioned that some ten or twelve years previously his own larynx had been examined by Babington at a place within a hundred yards of the society's rooms Mr Tilley wished to emphasize the work of the early laryngologists of this country, though, he added, possibly because they had not grasped the great opportunities of the use of the laryngeal mirror, the waters of laryngology were never seriously troubled until the day of Manuel Garcia's discovery in 1854 Garcia, who was not a surgeon nor a scientist, but a teacher of singing, made his discovery in Paris and came to London, where he published it, and where he spent the rest of his life, dying in his 102nd year Mr Tilley described how the idea of the mirror came to Garcia while he was walking in Paris, how he immediately put it to the test of experiment, and with what joy, in Garcia's own words, he "saw the glottis wide open before me and a portion of the trachea" Mr Tilley, through the courtesy of Mr Albert Garcia, was able to exhibit the original mirror, a jealously guarded heirloom in the Garcia family So great was the impulse which Garcia's observations gave to the study of diseases of the larynx that, said Mr Tilley, only a captious and pedantic critic would deny him the title of Father of Laryngology

After mentioning the work of Turck and Czermak and other early users of the laryngoscope for medical purposes, he described the debt which laryngology owed to Morell Mackenzie, whose two volumes, *Diseases of the Throat and Nose* would always remain a classic for accuracy of observation and clarity of description Mackenzie's diagnostic acumen was only surpassed by his marvellous dexterity At the same time, there was a great mistrust of the innovation in the great teaching hospitals, whose throat departments at that time were as a rule entrusted to junior surgeons or to physicians with no intimate knowledge of laryngology It was a common thing in those days for a student to leave his hospital and begin practice knowing little or nothing of diseases of the throat, with the consequence that his patients had to seek advice at the special hospitals, whose establishment incidentally deprived the general hospitals of a great deal of clinical material But thanks to the work of Henry Butlin and several others whom he named, in due course, one by one, the staffs of the large teaching hospitals recognized the situation, and placed their ear, nose, and throat departments in charge of men highly qualified in general medicine and with special training and experience in this branch of work Finally, Felix Semon founded the Laryngological Society of London Its success was almost instantaneous, and the Section of Laryngology, into which it was eventually transformed, had been, and still was, one of the most active of the Sections composing the Royal Society of Medicine Next to Morell Mackenzie, early English laryngology owed more to Semon than to anyone else He fought strongly against the prejudice which this new department of medicine had engendered, and on his retirement from practice he generously handed over the handsome testimonial presented to him to establish the Semon Lecture In concluding the historical part of his subject, Mr Tilley said that to those of them who had some experience of those difficult years it seemed incredible that a graduate in surgery in the University of London might now take the M S degree in otolaryngology

Turning to laryngology and clinical medicine, Mr. Tilley said that it was hardly necessary before such an audience to speak of the laryngeal mirror as an indispensable instrument, but even at this time of day the importance of an apparently trivial laryngeal symptom was often overlooked Chronic hoarseness or an alteration in the normal voice might be due to an intrinsic cause, or it might be a local manifestation of a general disease, or, again, it might result from a distant but restricted lesion What a tragedy lay in the tardy diagnosis of the causation of what seemed so trivial a symptom as slight chronic hoarseness, for the disease spread, and, when pain or slight stridor supervened, it was probable that only complete removal of the larynx would save the patient's life He pleaded once more that it should ever be remembered that chronic hoarseness of more than three or four weeks' duration demanded a laryngoscopical examination, because the pathological factors which might cause the symptoms were all more or less serious With regard to hoarseness as a local manifestation of a general disease, the laryngoscope might show slight primary congestion of one vocal cord, an early and typical manifestation of laryngeal tuberculosis due to a primary lesion in one or both lungs Without the laryngoscope many weeks or months of valuable time might be lost With regard to distant restricted lesions, not an uncommon example was aneurysm of the aortic arch Slight hoarseness might be the one and only early symptom of intrathoracic growth Central nerve lesions affecting the vagus should not be forgotten Again, chronic laryngitis might be a prominent symptom in certain diseases of the kidney, or might result from local factors, such as septic conditions of the nasal accessory sinuses, the tonsils, or the teeth But in such diseases as he had mentioned the laryngeal symptoms might be one of the earliest manifestations, and the laryngoscope provided the clinician with the only means by which the mind could be made alert to the various possibilities

Mr Tilley then went on to speak of developments which had followed the laryngoscope He mentioned Kirstein's work, and also that of Killian For all time the name of Killian as the founder of the method of which the late Chevalier Jackson was the most brilliant exponent would be remembered The demonstrations of direct endoscopy which Professor Chevalier Jackson carried out during his visit to London in the autumn of 1930—including one at the Medical Society of London—would be fresh in the

recollection. Mr. Tilley said that he had himself visited Professor Jackson's bronchoscopic clinic, and had seen many cases in which, by the removal of adherent mucus, freer aeration was secured. Professor Jackson had truly said that physicians might inspect the chest, palpate, percuss, and auscultate, and, with the aid of *x* rays, look through it, and while it redounded to their credit that they more often than not made an accurate diagnosis, it was equally true that this must be tentative until the lapse of time perhaps brought about a further development of symptoms which placed it beyond question. But to make the diagnosis early, direct inspection of the gateway of the lungs would often save the physician's time, and save also considerable mental and physical suffering to the patient, possibly even his life. The bronchoscope had again and again detected early malignant growth in the bronchi, and it was known that 87 per cent. of malignancy in the lung commenced in that region. These growths were of a relatively low degree of malignancy, which, after removal, might be very slow in recurrence, though, the speaker said, after experiences in which there had been recurrence many years subsequently to the first operation he would never use the word "cure" with reference to such cases.

"In conclusion," said Mr. Tilley, "one is sometimes tempted to wonder whether those handmaids of medicine, the laryngoscope and her younger sisters the bronchoscope and the oesophagoscope, have not reached their limits of use. But I am optimist enough to believe that in the direct inspection of the lower air passages and the oesophagus there remains a large field for the willing and earnest worker who aims to advance the science and art of medicine. He will find comfort in the words of the greatest of all Teachers: 'There is nothing covered which shall not be revealed'; and the student, furthermore, will gain encouragement if he grasps the truth—and perhaps the warning—embodied in those lines of Keats: 'So on our heels a fresh perfection treads, Born of us, but fated to excel us.'"

Mr. Tilley concluded his address by showing a large number of lantern slides, chiefly illustrating conditions revealed by the laryngoscope. He also exhibited a whole range of foreign bodies of surprising diversity which had been removed at various times from the air passages of patients.

Sir StClair Thomson proposed a vote of thanks, and referred to his long association with Mr. Tilley, dating back to 1893. The resolution was seconded by Mr. E. B. Waggett, who said that it had been very interesting to hear, within the compass of one address, of the various stages through which laryngology had advanced, capturing the service of such things as radium, *x* rays, the direct method, and so forth; but all these things, to those of them who had grown old in this branch of medicine, came as a natural growth or succession. Looking back, however, one comparison forced itself upon his mind—namely, that in his own young days the number of people who could see in the laryngoscope was only a few dozen, whereas now in almost every small town there was to be found a capable laryngologist.

ACUTE INFECTIOUS FEVERS

At the meeting of the Brighton and Sussex Medico-Chirurgical Society held on October 1st, Dr. Duncan Forbes gave his presidential address on the acute infectious fevers. He referred to the pandemic diseases and the high mortalities caused by these in England in comparatively recent times. With regard to the endemic diseases, the encephalitis following vaccination, small-pox, measles, etc., was shown to be both histologically and clinically distinct from encephalitis lethargica. The fact that encephalitis post-infectionism was not known to attack infants under 1 year of age seemed to render unnecessary any departure by public vaccinators from the old and thorough methods of the vaccination of infants of past years. The abandonment of the present pseudo-compulsory and cumbrous system was advised, and its replacement by free vaccination against small-pox and free immunization of infants against diphtheria at convenient centres. As an argument in favour of the immunization of the infant it was pointed out that 1 in every 13 infants born in Brighton contracted and 1 in every 153 died from diphtheria before reaching the age of 15. Immunization was well worth while up to 7 years, saving 1 in 29 from attack and 1 in 463 from death before that age. With regard to measles, whilst school closure to delay epidemics from the cold to the warmer months was advocated, the exclusion of contacts appeared to do no good, but rather harm, as whilst the exclusion of individuals did not prevent all susceptibles being infected, it allowed contacts to play during school hours with children under school age. Measles did little harm to healthy children over 5, and should be regarded as a useful form of vaccination. Puerperal fever was attributed as often due to interference, and frequently unnecessary interference, by the midwife and doctor. Isolation hospitals, as their name implied, were established for segregation rather than for treatment. Except in small-pox they had utterly failed in controlling the spread of disease. The danger of segregation as distinguished from the cubicle isolation of scarlet fever and measles was pointed out. Isolation hospitals should be used for diagnosis and treatment of diphtheria, complicated scarlet fever, typhoid fever, puerperal fever, cerebro-spinal fever, and ophthalmia neonatorum, in all of which institutional treatment was necessary. Typhoid fever could be nursed in general hospitals if the nurses were protected by vaccines as they were in isolation hospitals; there was no danger of rendering a nurse more liable to attacks from diphtheria or typhoid by immunizing her whilst nursing these diseases. In conclusion, Dr. Forbes remarked on the futility of the old methods of disinfection, and advised the laundering of pillow slips and sheets with a spring clean as an effective substitute.

At the annual meeting of the Royal Academy of Medicine in Ireland, held on October 2nd, the following officers were elected: *President*, Professor T. G. Moorhead *General Secretary*, Dr. T. P. C. Kirkpatrick. *Secretary for Foreign Correspondence*, Mr. William Doolin.

The North of England Tuberculosis Society, being the Northern Branch of the Society of Medical Officers of Health, has held five meetings during the past year—one at Stannington Sanatorium, two at the Medical Institute, Newcastle-upon-Tyne, one at Wolsingham Sanatorium, and one at Barrasford Sanatorium, when officers were elected for the ensuing year.

The National Adoption Society has issued a report covering the two years 1929 and 1930, during which 121 boy infants were happily settled as compared with 332 girls. The hope is expressed that prospective adopters will consider the urgency of need in respect of boy babies, a very large number of whom await adoption. A hostel at Connaught House, Acton Lane, was opened in the late summer of 1930 for the temporary care of babies for whom suitable adopters have yet to be found. It is anticipated that the society will now have to raise an additional annual sum of £500, since the expenses of the hostel cannot be met out of the present income, and parents' contributions are too often inadequate. Further information may be obtained from the secretary of the society, 4, Baker Street, W.1.

Reviews

DISORDERS OF THE THYROID

The borderline between health and disease is difficult to define, but as knowledge grows conceptions of disease alter, and many states, compatible with a normal or nearly normal existence, are being recognized as the early stages or mild forms of the more serious states that have for long been regarded as diseases. This is the aspect of diseases of the thyroid gland that LUCIEN DAUTREBANDE takes in a monograph entitled *Physiopathologie de la Thyroïde*,[1] and, in addition, he is pleading for a wider use of iodine in the treatment of thyroid disorders. There is little that is new in the chapters on physiology and pathology, but these sections of the book present the subject in a kindly critical manner and deal fairly with the work that has been accomplished in many countries. They are worth reading, for they show clearly what is known, and point out the large gaps in our knowledge.

In the diagnosis of the various thyroid disorders the author relies almost entirely on estimations of the basal metabolic rate, and if clinical states do not fall into line with metabolic rates they are either ignored or the case is classified among "Les Discordances." A patient who presents the clinical manifestations of a simple goitre, but whose metabolic rate is raised, is classified as an example of "mild toxic adenoma"; and a patient with symptoms of intoxication, but with a normal or low metabolic rate, is placed among the simple goitres or the cases of hypothyroidism. To have two classes of "toxic adenoma," mild and severe, may be helpful in the grouping of cases, but is surely unsound if there is no essential difference between them. The author appears to believe that there is no essential difference between the various types of thyroid disorder, for he seems to have the wide point of view, gradually gaining ground among those interested in thyroid disease, that the gland is in some way a deficient gland no matter what the clinical picture that develops. It seems the more unnecessary, then, for him to subdivide his cases to a greater extent than usual. Under each heading there is an admirable collection of case reports, and it is probably for the sake of the grouping of these that the diagnostic differentiation is somewhat overdone. As with diagnosis so with treatment; the basal metabolic rate is used as the indication for more treatment or for the cessation of treatment, and is the criterion by which treatment is judged. Dr. Dautrebande must have at his command more accurate methods of estimation of metabolism than are attained in most clinics, and he must obtain basal conditions more surely than most workers are able to do, if his conclusions are justified and if his regulation of treatment in this way is sound. The difficulty in obtaining basal conditions in observations on human beings is sufficient to throw doubt on the validity of his conclusions, both as to diagnosis and to treatment. Diseases of the thyroid gland continue, as a rule, for many years, or for most of a lifetime, during which the clinical manifestations vary within wide limits, and the metabolic state also is subject to great variation; the author recognizes this, but has been unable to resist labelling his patients as examples of one or other variety of thyroid disorder.

It is in the use of iodine that the author has a definite contribution to offer. He has failed in Belgium to find patients who are made worse by iodine, and considers that iodine is useful in the treatment of patients with nodular goitres, as it is generally agreed to be in those with frank exophthalmic goitre. This is not a new conception of iodine therapy, but his opinion, after careful study, is of value. As a rule he uses iodine in much the same way as other workers who consider treatment by it to be of much greater value than a pre-operative measure, except that he uses larger doses than are usual in this country. When, however, the patient is not showing further improvement, or is relapsing, with two or three administrations a day, he obtains further improvement by means of the same daily amount given in small doses several times a day, even as often as fifteen times in twenty-four hours. The author has already published his method of subdivided dosage, but it deserves a careful trial in this country, and the book will be of service if its publication results in confirmation of the good effects that are claimed for this method of administration. The monograph concludes with an extensive and valuable bibliography.

A HARVARD SURGICAL TEXTBOOK

The average textbook of surgery tends to be very stereotyped in its presentation, and it is probable that on account of this the "saturation point" in the publication of such volumes is fast approaching; but that there is room for originality even in a textbook is amply demonstrated by the appearance of a new volume from the Harvard Medical School.[2] This has been edited and largely written by Dr. JOHN HOMANS, and is compiled from lectures and other writings of the staff of the school, which includes such internationally well-known names as those of Cushing, Osgood, and Richardson. Homans, using the information provided in these lectures, has reduced the material to a uniform style of presentation, which is both exceedingly attractive and original; indeed, we have rarely had such pleasure in reading a technical book of this type, and can appreciate that the author, as he states in the preface, "found the task of writing it a joyous one," as that of reading his composition certainly is. It would be difficult to describe accurately the "atmosphere" which the author has created, if the word dare be used in connexion with a scientific work, yet undoubtedly the colloquial language of the lecture theatre and the little personal touches which appear here and there throughout the book do give it a very unusual and individual character. This will, perhaps, best be explained by quoting from one of the short historical sketches which precede each chapter, and not only add to its educative value, but help to fix the interest of the reader; these are intended to be informal, often anecdotal. Some of the matter is inevitably merely diverting, but most of it is a tale of the classic work of great men, living and dead. Thus

> "Nicholas Andry (1741), a French professor of medicine, coined the name, orthopaedia—the straight child—for the book of his ripe old age, and some eighty years later another Frenchman, Delpech, wrote a great work 'L'Orthomorphie,' and became the true founder of the specialty; he performed the first subcutaneous tenotomy. His remarkable career was cut short at the age of 55, when he was shot by one of his patients upon whom, it is said, he had operated for varicocele, a tragic commentary upon an operation which has never borne a very good name. But if orthopaedic surgery was born and baptized in France, it was not of pure French stock. On one side its lineage must be traced to the bone-setters, who in England and Wales were particularly skilful and influential. In John Hunter's day, a Mrs. Mabb drove her carriage and pair into London to take charge of the dislocated limbs of the nobility and gentry."

Such passages abound throughout the book, and afford relief to the more descriptive and solid paragraphs, which, however, are so well written as to need little help in this

[2] *A Textbook of Surgery.* By John Homans, M.D. With a special bibliographical index, and with illustrations by Willard C. Shepard. London: Bailliere, Tindall and Cox. 1931. (Pp. xii + 1,200; 513 figures. 40s.)

respect. Lest it be thought that the systematic and scientific aspects of the subject might have suffered any eclipse on account of the style adopted, it must be recorded that they are dealt with in a most adequate manner, practically the whole realm of surgery being covered, with an excellent sense of proportion. In smaller print at the beginning of each chapter the salient points in the anatomy and physiology are recapitulated, and in some instances definitions of special terms are given. There are few points of surgical interest which are not touched upon, even the rarer diseases receiving a short paragraph; and, where matter for controversy arises, the author's summing-up is particularly well balanced, and indicates a judicial mind of wide experience. In addition to a good general index, there is a really useful bibliographical index, not too exhaustive for the practical needs of the student, and yet full enough to contain all the essential references.

The illustrations demand separate consideration, and the author and artist are to be congratulated upon their choice and lucidity. So accustomed have we become to the photographic half-tone illustrations in American textbooks, which, while perfectly reproduced, sometimes tend to obscure the main feature by their very excellence, that the line drawings appearing throughout this book only emphasize its distinctiveness, and form a fitting corollary to the text. Like the text, too, they are at times unconventional—for example, drawings to illustrate the types of accident in which certain fractures and dislocations are sustained. Even the radiograms have been reduced to line drawings and, interestingly enough, have lost nothing of lucidity or teaching value in the process.

Altogether this is an excellent textbook, and one that may be very cordially recommended to the student searching for escape from the stereotyped presentations of the subject with which he is so familiar.

HIGH BLOOD PRESSURE

In *Arterial Hypertension*[3] Dr. E. J. Stieglitz gives a comprehensive review of the common condition which is responsible for 140,000 deaths from cardiac failure annually in the United States of North America. While quoting Allbutt, who condemned the term hypertension, he prefers this to high blood pressure, as the underlying factor is in the arterial system and not in the blood, but he regards the adjective "essential" as particularly obnoxious on account of the inference that the etiology is of minor significance merely because it is obscure, whereas treatment depends on recognition of the responsible factors. These are numerous, and are summed up by the statement that "the etiology of hypertension is anything which irritates the arterial musculature"; there are, he considers, two phases of causation: the "irritating" factors, such as heredity, which is irrevocable, past renal damage, and previous infection, and the "perpetuating" factors—namely, vascular fatigue and the resulting hyperirritability. The symptoms of high blood pressure are due to complications caused by arterial disease; these are impairment of the local circulation, with resulting tissue anoxia, starvation, and imperfect removal of metabolic products. A hopeful view is nevertheless taken as regards prognosis, which is dealt with in considerable detail. In connexion with the reduction of blood pressure by vaso-dilator drugs attention is drawn to the effect of sodium nitrite given by the mouth a relatively insoluble nitrate, such as erythrol tetranitrate, which is slowly broken down and absorbed by *Bacillus coli* in the intestinal tract, a change accelerated by the presence of vascular fatigue, and so the hyperirritability. The administration of 5 to 10 grains in capsules three times daily is followed by a very gradual fall of blood pressure, and as this occurs the dose is reduced. A comparison of the results obtained in this way with those produced by sodium bromide showed that more permanent benefit followed bismuth therapy. This volume represents lectures given for some years at Rush Medical College, and reviews the literature reflected in a list of more than eleven hundred references.

[3] *Arterial Hypertension*. By Edward J. Stieglitz, M.S., M.D. Edited by I. Woolvatt, M.D. London: Milford, Oxford Univ. Press. 1930. (Pp. xvi + 280; 21 figures. 25s. net.)

AN OUTLINE OF THE UNIVERSE

Mr. J. G. Crowther in *An Outline of the Universe*[4] has, in 376 pages, put a girdle round the space-time continuum in which our poor small earth pursues its bewildered and elliptical course. Whether the universe be finite or infinite, a concourse of protons and electrons mutually attracting and repelling each other or an idea in the mind of God, a material fact or a mathematical fancy, there are some things known about it which should perhaps be as important to the average man and woman as the Davis Cup or the probable winner of next year's Derby. As the author points out in his preface, there has recently been an excessive concentration on the particular and a dangerous neglect of the general. For every specialist the universe is bounded by his specialty. We are running the risk of becoming more specialized than the ants and the bees. Man has arrived at the top of the zoological tree by freely exploiting his adaptability to environmental demands. He has preserved his anatomically primitive forelimb from the doubtful advantages of specialized function, and so has avoided travelling the monotonous path of the tortoise and the cow. If his forelimb becomes an extension of the gear lever of a machine, his stomach a receptacle for synthetic foods, his special senses detector valves for mechanical vibrations, then he may in the end be extinguished as were the great orders of reptiles in the Mesozoic period. One complexity leads to another, one specialization to another; but regression to an earlier, more primitive state is an infantile method of flight. What is needed is a return to the Greek ideal of the harmoniously balanced man: "The old idea of comprehensiveness waned until to-day it is hidden by the inco-ordinated pile of knowledge gained by specialization."

Mr. Crowther's book is a praiseworthy attempt to restore this idea of comprehensiveness. The way of restoration has already been shown by H. G. Wells, who in his masterly syntheses of the ancient and modern worlds has done more than any living writer to present to the common reader a unity out of the apparent diversity of known facts. If a man would know what the universe is like, what island universes are, what is the nature of stars and planets, how the modern atomic theories were formed; if he wishes for information about heredity, evolution, physiology, the work of Pavlov, the mentality of apes, or the origin of civilization—then he should read this book.

There is nothing undreamt of in Mr. Crowther's philosophy. "Mysticism," he says, "is the product of those who fail to understand, the substitute for comprehension and the margarine of philosophy." "Human behaviour to the objective observer is in principle completely describable in these terms"—that is, in terms of excitation and exhibition. "It is more important to produce a large surplus of wealth than to study how wealth could best be used." "Since political is secondary to productive technique the fate of the future rests on production." How he piles it on! Has it not occurred

[4] *An Outline of the Universe*. By J. G. Crowther. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1931. (Pp. xvi + 376; 150 illustrations. 12s. 6d. net.)

to him that it is very difficult for one set of conditioned reflexes to explain another set of conditioned reflexes in terms of conditioned reflexes? It is the insoluble problem of the behaviouristic school of psychology. Let the cobbler stick to his last and Mr. Crowther (we say it in all respect) to his science.

THE EFFECTS OF ALCOHOL

It is very difficult, perhaps impossible, to write a book about alcohol, and the biological and social effects it may produce, without bias. Probably, therefore, such a book when composed by a considerable number of authors with their varied experiences and opinions may be preferred to one by a single author, or by two authors closely associated in their views. Further, when a book of such multiple authorship is subject to a dual editorship, under the general supervision and authority of an investigatory committee consisting, besides the authors, of other eminently qualified persons, impartiality and the scientific point of view may be approached as nearly as is possible. A volume of such a character, produced under such auspices, is *A Review of the Effects of Alcohol on Man*,[5] recently published by Victor Gollancz. The list of persons responsible for it need not here be given; they are all recorded, with their respective spheres, at the beginning of the book itself. It should be said, however, that the volume is moderate in size—three hundred pages in all—beautifully printed, well paragraphed, sufficiently indexed, and with a useful and fairly complete bibliography to each chapter. It does not purport to record any original research, but professes to give an impartial and up-to-date review of the effects of alcohol on the human body and mind, and of the part it plays in relation to disease and the practice of medicine. It is manifestly impossible, even if it were desirable, to summarize such a book, and a little difficult to indicate the fullness of its contents. Every part of it is carefully written and documented, and each of its chapters has its peculiar merits. Naturally, it does not result in any dogmatic pronouncement, and its conclusions are not seriously different from those which are now mainly agreed and recognized by medical men and others who have seriously studied the matters with which it deals. There are some evidences of differences of opinion on minor questions among its various authors, but it reveals a uniform tone and general agreement when viewed as a whole. By many readers, no doubt, Chapters IV and V, on the mental effects of alcohol and its relation to mental disorder, and the last chapter, on heredity, may be considered the most important. Throughout one gets the impression that, in the conscious striving after a judicial attitude, everything that could possibly be said in favour of the use of alcohol has been noted down; but, especially if read in connexion with such a book as that on *Alcohol and Human Life*, by Dr. Courtenay Weeks, noticed in our columns two years ago, it will prove a valuable work of reference and a volume which will, as claimed in its preface, "assist the unprejudiced person who wishes to survey the whole field of evidence and form his own opinion."

NOTES ON BOOKS

In their *Introduction to Mental Hygiene*,[6] Professor Ernest R. Groves and Phyllis Blanchard have attempted to synthesize what may be called the "mental hygiene movement," and the result, if not completely satisfactory—as could hardly be expected—is certainly interesting and helpful. Although at times the authors seem to be unduly discursive, and perhaps necessarily superficial, yet they have compiled a volume of very considerable practical value, which indicates the main lines of preserving mental health in spite of difficulties encountered in various environments and at different times of life. The book is correctly named, since it should form an introduction to larger textbooks on some of the many topics dealt with in detail.

Ritual: Psycho-analytical Studies,[7] is a translation into English by Dr. Douglas Bryan of the second edition of the German book in which Dr. Theodor Reik discusses from the Freudian point of view four forms of religious ceremonies—namely, couvade; the puberty rites of savages; Kol Nidre (part of the programme of observing the Jewish Day of Atonement); and the Shofar, or Ram's Horn. For the most part the book represents an attempt to trace in these observances a psychological basis—the gratifying of certain instinctive demands. The argument in the case of couvade (a ceremonial retirement of the father to bed after childbirth) is that there is implicit in it a latent infanticide motive, the overcoming of which marks a step forward to a new orientation in which individual demands are to be subordinated to those of the family. In his examination of the puberty rites of savages Dr. Reik draws some interesting parallels between the mental life of primitive humanity and that of neurotics. Circumcision, a hostile act, represents the symbolic punishment and prevention of incest, and the ritual "killing" denotes the punishment and prevention of parricide. This is followed by a "resurrection" stage, opening the way for a new and legitimate sexual life. The two Jewish ceremonials are analysed similarly, the Kol Nidre being interpreted as a release from unconscious obligatory strivings, and the Shofar as a warning against parricidal urges, as well as a promise of expiation of past guilty desires of this kind. The intensely deep analysis and the ingenuity of interpretation may render the general conclusions unacceptable to some, but as an illustration of the Freudian outlook on certain trends discoverable in many forms of religion the book is admirable. It will stimulate thought, even if it does not induce agreement.

The third edition of the *British Waterworks Year Book and Directory with Statistical Tables*, 1930–31,[8] just published by the British Waterworks Association, contains a mass of information relating to waterworks undertakings in Great Britain and Ireland, and in some of the British waterworks over-seas. The book is divided into three parts: (1) directory, (2) statistical tables, and (3) general information. Particulars of 871 water undertakings are recorded as compared with 285 in the 1928 issue. The value of the directory part has been enhanced by cross-references to the names of towns and places within the limits of supply of the larger water undertakings. The statistical tables furnish particulars as to sources of supply; extent of catchment area; storage or subsidence reservoirs; walls and springs; and engine power.

The Annual Charities Register and Digest[9] gives essential information of the societies, associations, and other bodies that provide relief in all kinds of affliction and distress, whether temporary or permanent. We have frequently remarked in these columns on the intelligence, care, and lucidity that distinguish this handbook, the thirty-ninth edition of which has just been published.

We have received the Proceedings of the second Argentine Congress of Surgery[10] held at Buenos Ayres under the presidency of Dr. Eduardo Belaustegui from July 13th to 19th, 1930. The principal subjects for discussion were the post-operative complications of appendicitis and the treatment of peptic ulcer, Pott's disease, mammary cancer, and sacro-coxalgia.

SATURDAY, OCTOBER 17th, 1931

INSURANCE SICKNESS CLAIMS

In June last the Ministry of Health issued to every insurance medical practitioner, to Insurance Committees, and to others, a memorandum on certification of incapacity for work. As the result of certain investigations that it had undertaken, the Ministry concluded that the main cause of the great increase in admitted claims to sickness and disablement benefit of recent years was laxity of certification on the part of insurance practitioners. This was a very serious charge to make, and its seriousness was not much mitigated by the statements that the great majority of insurance practitioners were not involved in the charge, and that in the case of most of those who were so involved it was a misunderstanding of the insurance position, or a misplaced humanitarianism, rather than wanton carelessness, or any less worthy motive, that was at the bottom of the error. It seems clear that the broadcasting of such a memorandum could be justified only if, in the opinion of the Ministry, the conclusions stated therein were unequivocally established, and if the offences against which it was directed were at least widespread among insurance practitioners. The memorandum was issued without any consultation with those who had a right to be heard before they were publicly accused, and we believe its issue was without justification on either of the grounds just stated. Immediately, in the *Journal* of June 20th (p. 1078), we commented upon the memorandum itself, and on the circumstances of its issue; and what was then said has renewed importance in view of the fact that the Insurance Acts Committee has now issued a considered reply, which has been sent to the Ministry, is to be placed before the Panel Conference on October 22nd, and was printed in the *Supplement* to our last issue.

There is no dispute as to the fact that there was a great increase in the number of admitted claims to sickness and disablement benefit during the years 1922 to 1929, as compared with similar claims between 1913 and 1921. It is the nature and cause of this increase which it is desirable to discover, for, if it were to continue, it must lead either to the bankruptcy of many approved societies, or to a radical reconsideration of the actuarial basis on which national health insurance was originally established. This basis, though the best possible under the circumstances, was admittedly drawn from an insufficient volume of experience, and may yet have to be reviewed. Nor is there any dispute as to the other facts which are set out in the Ministry's memorandum. It is the inferences drawn from those facts which are challenged. We believe the Ministry's inferences to be erroneous, and regard the alternative and contrary inferences set out in the reply of the Insurance Acts Committee as being not only much nearer the truth, but now well established.

Certification as to the moment, or day, at which incapacity for work actually begins or ends can rarely be a matter of absolute exactitude. It is, moreover, admitted that, from the commencement of the national health insurance system, there have always been some cases in which, for a variety of reasons, practitioners have certified as incapable of work persons who are not incapable in the technical sense of the Insurance Acts and Regulations. Insurance practitioners themselves have suggested ways in which such improper certification should be dealt with and prevented. These things being accepted, and ignoring some other factors which the Ministry of Health dismisses as of no account, but to which the Insurance Acts Committee attaches a certain degree of minor importance, the difference between the Ministry and the Committee is broadly this. The Ministry says that the *increase* in the number of admitted claims to benefit during the last eight or nine years, as compared with the previous similar period, is due to an increase in the laxity of medical certification, while the Committee says that it is due mainly to an increase in the number of legitimate claims made by insured persons. It is clear that the effects under consideration could have been brought about by either of the alleged causes, but surely there can be no doubt about the relative probability of these causes. To the question, "Why should the standard of certification of practitioners suddenly have deteriorated in the year 1922 and have continued on a lower plane ever since?" the Ministry offers no answer. To the corresponding question, "Why should the legitimate claims of insured persons have begun to multiply in the year 1922 and have continued at a higher rate since then?" the Insurance Acts Committee gives a reply stating categorical reasons which appear convincing.

We need not attempt to summarize or recapitulate here the facts adduced or the arguments used by the Insurance Acts Committee in support of its thesis. The reply itself should be read, with the emphasis placed on the major propositions and explanations set out above. The general considerations all point to the one conclusion; and such statistical evidence as has been brought forward by the Ministry appears either to be insufficient to allow of any reliable inferences being drawn therefrom, or to be compatible with, or favourable to, the explanation put forward by the Insurance Acts Committee. For instance, the facts that the increase is not in the duration of claims, but in the number of persons claiming, that it is in short illnesses and not in long ones, and that it is among the younger insured persons and not the older, are all consistent with the contention of the Insurance Acts Committee, and appear inexplicable on that of the Ministry. Further, from the fact that the average duration of incapacity claim is less than three weeks, it seems necessarily to follow that, on reference after the tenth or twelfth day,

and allowing a further four or six days before examination on such reference actually takes place, a substantial proportion of persons under certification will, in the ordinary course, then have declared off the funds or be found not incapable, and that therefore no sinister significance need be attached to this.

In face of such facts and considerations it is hard to understand why the Ministry should have dismissed as a quite inadequate explanation of the increase "a tendency of persons incapable of work, who would not have claimed in earlier years, to claim under present conditions." Even stranger was the remark that "it has never been suggested" that such cases "are sufficiently numerous to have a substantial effect." In our previous article on the Ministry's memorandum we said: "On the contrary, this *has* been suggested, and is here and now suggested, as producing a substantial effect, and even as being a main factor in the situation." We would now go further. It appears to be established beyond reasonable doubt that this is *the* main factor.

HEALTH MATTERS IN PARLIAMENT

To the relaxed mind, as the Faraday celebrations reminded the public, great and valuable thoughts often come. Neither Ministers nor Members of the late Parliament had much chance of such inspiration. With an exiguous majority, in part unsecured by any firm ties and with an overloaded programme, the Labour Government drove Parliament hard, continued its first session more than a year, multiplied committees of inquiry, and overtaxed the standing committee system of considering Bills. In the few weeks that the National Government directed Parliament, pressure on Members' time and attention was still greater; leave of absence was all but unprocurable. This overcrowding of the programme has not produced commensurate output of first-class legislation. Some Bills were rejected or held up "in another place." Some were abandoned by their authors. Some which passed into law are patchwork measures, of no permanent validity. The struggle to cope with the immediate task, and the unstable balance of parties, prevented men seeing ahead. Even at the end of July, 1931, scarcely any Members descried the monetary crisis or the departure from the gold standard.

So distracted and overworked a Parliament was not likely to make a great advance in health legislation, and no public result did in fact ensue from the Government's institution of an inquiry into the correlation of all forms of national insurance. But the House of Commons was sympathetic to pleas for improvement in public health services. When it received from the House of Lords the Mental Treatment Bill it carried this invaluable measure to provide for the remedial treatment of uncertified cases. Members who voiced the old suspicions of alienists and of the Board of Control had few supporters. The Government also carried a Housing Bill, which should facilitate slum clearance. In the Road Traffic Bill it incorporated an obligation on motorists to declare their physical fitness, and also an obligation, though an incomplete one, to provide for payment to hospitals for treatment of certain road casualties. Less success attended the Poisons and Pharmacy Bill, which failed to pass this session because of the conflicting demands from farmers and chemists. Maternal mortality was upon the conscience of the House, but the large scheme for national preventive measures, foreshadowed by the Labour Government, had not been seen before the Dissolution.

Health was more often and better discussed on the Ministry of Health Estimates than it had been in the preceding Parliament, when these debates became monopolized by wrangles about poor relief. The abnormal increase in claims for sickness benefit, the fear that some approved societies might not be able to provide all the benefits they had promised, were fully debated in the Commons. Psittacosis, the provision of doctors for the Army, the recognition of Indian medical degrees, the future of the Royal Veterinary College, and the proposed municipal supply of radium in Hull, were subjects which the House debated keenly. The interest in health and medicine of Mr. Arthur Greenwood himself was never in doubt, and was signalized on April 9th, 1930, by his announcement that the Government was prepared to pay up to £250,000 towards the establishment at Hammersmith of the British Post-Graduate Hospital and Medical School. Scottish public health received due attention. Parliament passed an Act making larger monetary provision for medical service in the Highlands and Islands. Another Act, promoted by Dr. Walter Elliot, facilitates the supply of milk to Scottish school children.

In the House of Lords Lord Dawson and Lord Moynihan have contributed brightness as well as authority to medical debates. In the Commons the medical profession was represented more numerously than ever before, and it became possible for the Parliamentary Medical Committee to be restricted to Members or Peers with a professional qualification. A Socialist Medical Group also appeared, which, inspired by the late Dr. Ethel Bentham, conducted a preliminary campaign in favour of a national medical service. The British Medical Association's proposals for a general medical service were received and noted by the Government and by medical Members, but were not publicly discussed in Parliament. Mr. Somerville Hastings's Bill for regulation of proprietary medicines, introduced last session, did not secure facilities. Bills presented by non-medical Members for the "protection of dogs" against experiment and for the registration of osteopaths went no further towards the Statute Book. In brief, the late Parliament was well disposed towards medicine, and desirous of improving public health. An overcrowded programme, and a lack of clear direction, made this good will less fruitful than it might have been. In the Parliament which is called to assemble on November 3rd lack of money and preoccupation with the national emergency may preclude much further advance in health legislation.

RURAL HYGIENE IN EUROPE

The Council of the League of Nations, at the first meeting of its recent session, received an interesting report from the European conference on rural hygiene, held lately at Geneva under the presidency of Professor Pittaluga, director of the National School of Medicine at Madrid. The most striking part of the report concerns the methods of furnishing effective medical assistance to the rural populations. The view was unanimously expressed that 2,000 was the maximum number of persons who could be given proper attention by a duly qualified medical practitioner. In Germany there is, on the average, one physician to 2,317 persons in the rural districts, while in cities the proportion is 1 to 786. The conference was informed that, despite the introduction of the motor-car and the telephone, the average area served by a physician in the rural districts of Germany is about 10 square kilometres, as compared with very nearly 40 square kilometres half a century ago. In Italy there is one medical *condotto* (a doctor appointed to attend the indigent, who are entitled to free medical treatment and drugs) to 3,603 inhabitants, not exclusively rural; but when account is taken of that part of the population which has no recourse to the *medici condotti*, the number of persons served by each doctor is far less and approximates to the standard proportion. It was also considered desirable by the League conference that the number and distribution of pharmacists and doctors who dispensed their own drugs in rural districts should be such as to ensure that all prescriptions for the population were rapidly dispensed, and, further, that rural doctors should be in a position to utilize the services of centres of diagnosis and specialized treatment. Such centres for various purposes —maternity and child welfare, tuberculosis, venereal diseases, cancer, and school hygiene—exist in all European countries. Sharp differences of opinion were apparent as to the part which such centres should take in giving treatment. In Germany no treatment whatever is given at the centres; in France, anti-venereal treatment alone is given, while in some countries all necessary specialized treatment is furnished. An adequate scheme of rural medical assistance was held by the conference to imply hospital facilities (one hospital for a population of between 20,000 and 30,000). also the availability of medical specialists, who should keep in touch with the patient's doctor, informing him of the results of the examination and treatment, and, finally, the service of laboratories, the simpler examinations and analyses being made in the hospital laboratories and the more complicated in specially equipped institutions. In the ideal plan of medical assistance visualized by the conference, a many-sided collaboration is necessary, including the public authorities, the medical profession, the health insurance organizations, the mutual benefit societies, and bodies engaged in voluntary social work. It was pointed out that in Great Britain, France, and Germany national health insurance, with public assistance for non-insured indigents, is a means of bringing effective medical service to the rural populations. In Italy the system of *medici condotti*, already explained, is employed. Out of 20,000 doctors in Italy more than half participate in this service. The methods of attracting doctors to rural districts were discussed; these include, in various European countries, the employment of doctors by insurance institutions, their employment by public assistance authorities for the treatment of the poor, and by health authorities for vaccination and other preventive work. In some areas, like the Highlands and Islands of Scotland, other measures are adopted, such as the assurance of a minimum salary, and the provision of lodging, means of transport, payment of mileage, and payment of medical school fees, on condition that the recipient shall undertake practice in a rural area for a given period. Some of these methods are also used to ensure a sufficient supply of nurses and midwives. In Italy an endeavour is made to attract doctors to the countryside by raising their salaries and by limiting free treatment to the indigent; in that country the doctor is entitled to a pension on retirement, and in case of death by an infectious disease contracted on service his children are provided for by the State. Many other interesting recommendations were made with regard to public health services in rural districts. The scheme envisaged includes the setting up of a primary health centre, the simplest agency adapted to the public health needs of the smallest rural area, and a secondary health centre, which would be a more fully developed organization than the primary, on account of its greater completeness of equipment, larger personnel, and wider scope of work.

UROBILIN AND UROBILINURIA

Urobilin, discovered by Jaffé in 1868, is a substance of interest in connexion with all haemolytic diseases—such as pernicious anaemia and haemolytic jaundice—and also with many diseases of the liver. We knew that this pigment was derived from bilirubin, the iron-free part of the haemoglobin molecule, which, when red blood corpuscles are destroyed because they are old or because of some disease, was carried to the liver for excretion in the bile. We knew, too, that in the intestine bilirubin was normally acted on by micro-organisms and converted into urobilinogen, a colourless compound easily oxidized into urobilin. These matters were clear, but the puzzle had always been to account for the occurrence of urobilinuria in a variety of diseases. Many explanations have been offered in the past, such as local formation of urobilin in the kidneys from excess of bilirubin in the circulating blood, and local formation in the liver, both under similar circumstances and also in hepatic damage or insufficiency. Hayem's old dictum of urobilin as *un pigment du foie malade* has often been quoted. In recent times local formation by cells of the almost omnipotent reticulo-endothelial system has naturally been suggested. Finally, there is the very old hypothesis that urobilin is absorbed into the blood from the intestine (especially when present in the bowel in excess) and, escaping the clutches of a damaged liver, reaches the kidneys for excretion in the urine. The problems involved attracted many workers, but remained unsolved. In 1925 Elman and McMaster,[1] working at the Rockefeller Institute, investigated the subject in animals with great thoroughness and with new and improved experimental methods.

[1] Elman, R., and McMaster, P. D.: *Journ. Exper. Med.*, 1925.

Their results showed, first, that microbic action is essential for the changing of bilirubin into urobilin, and, secondly, that urobilin is formed in only two situations in the body—in the intestine (the chief site), and in the biliary tract—but only if microbic infection of the bile exists. Urobilin from the intestine reaches the blood when the liver is damaged and partially incompetent, or when (as in the haemolytic anaemias) urobilin is formed in excess in the intestine, and, when absorbed, passes the liver simply by first overloading it. In supporting this view, Rolleston and McNee[1] conclude that "urobilinuria is not pathognomonic of any one morbid condition, its main diagnostic significance, apart from its occurrence in haemolytic anaemia, pernicious anaemia, and chronic haemolytic jaundice, being that some bile is entering the intestine, and that the functional activity of the liver is either very considerably impaired or that there is infection of the bile ducts." It is thus seen that the testing for, and recognition of, urobilin or urobilinogen in the urine has a very definite importance in clinical medicine; and for this reason we welcome the very complete recent monograph by Marcel Royer of Buenos Ayres dealing with the whole physiology and pathology of urobilin.[2] This monograph of nearly 200 pages covers the entire subject so thoroughly that no criticisms seem worth while. Moreover, each chapter is followed by a comprehensive international bibliography brought right up to date. Royer's book certainly gives to us for the time being the last word on all the possible relations of urobilin to clinical medicine.

FATHER DAMIEN

We do not know what demand there may be for another "life" of Father Damien, who gave up his life to the lepers of the North Pacific Ocean, nor does Miss Irene Caudwell think it necessary to offer any apology for the appearance of *Damien: The Leper Saint*.[3] Yet, as the actions of the just always "smell sweet and blossom in the dust," this pious tribute to the hero's memory is sure to be welcome. His doings were the subject of a good deal of controversy at one time, in which R. L. Stevenson took a share, but there is no excuse for a renewal of the argument now. Miss Caudwell draws a taking picture of the gentle philanthropist who gave health and life itself to help his fellow men. Joseph de Veuster—Father Damien as he was to be—was born in 1840 of peasant stock in the neighbourhood of Malines and Aerschot, place names which were to assume such a sinister sound in the great war. He was always a quiet child, and early showed his religious proclivities. He was educated at the University of Louvain. His brother, also a priest, had been selected to go to Hawaii, and, on his being struck down by typhus, Damien volunteered to go in his place. He had a tedious five months' voyage, and landed in 1864 at Honolulu. A decree of banishment for lepers was promulgated in 1865. The lepers were sent to the island of Molokai, and in 1873 Damien asked his ecclesiastical superiors to send him there in spiritual charge of them. He was then thirty-three years old, and for the next fifteen years he devoted himself to the lepers, dying himself of leprosy in 1889. When his death became known in England a movement was started to commemorate his life and death, and to carry on his work among lepers. King Edward VII, then Prince of Wales, presided at a public meeting at which it was decided, among other things, that a Damien Institute should be established for the study of leprosy, and that a detailed inquiry should be made into the condition and betterment of lepers in British India and other British Dominions. He had not lived in vain, for the interest which his romantic self-devotion had aroused led to widespread investigations and discussions, so that leprosy is no longer the hopeless disease which it was when Father Damien first landed in Molokai.

ADVERTISEMENTS OF FOOD PRODUCTS IN AMERICA

The American Medical Association has established a special committee to control the food advertisements that appear in its journal, in the same manner as the Council on Pharmacy and Chemistry already controls the drug advertisements. The reasons for this step are explained by the editor, Dr. Morris Fishbein, in a recent article.[1] The new knowledge of nutrition that has grown up during the last twenty years has had a pronounced effect on advertising in medical journals. Formerly, the chief substances brought to the notice of the profession by this means were pharmaceutical preparations and biological products, but in recent years the advertisement of food products has increased steadily, and to-day the space occupied by the latter type almost equals that occupied by the former. As Dr. Fishbein points out, our knowledge of nutrition is not only new, but very incomplete. Yet, notwithstanding the lack of exact information on which to make definite claims for various natural as well as synthetic food products, both the medical profession and the public of the United States have been deluged with announcements concerning the health-giving qualities of such preparations. No one will be surprised to learn that the committee set up by the American Medical Association to regulate the advertisement of foods has found its work strenuous, time-consuming, and extremely difficult. The credulous and lop-sided attitude of the public towards diet is a direct encouragement to exaggerated claims in advertisement. "The American people," Dr. Fishbein says, "are given to all or nothing policies in what they do for health. If they are told that the consumption of a certain amount of orange juice is healthful because it provides vitamin C and tends to overcome acidosis, they are likely to drink so much orange juice as to upset the digestion and to make impossible the taking of additional necessary food substances. If they are told that vitamins are healthful, they buy anything for which a vitamin claim may be made." Hence the phraseology of the advertiser is extravagant in order that he may impress the group to which he appeals. The general purpose of the committee is "to prevent or discourage unwarranted, incorrect, or false advertising

[1] *Journ. Amer. Med. Assoc.*, vol. xcvii, No. 2, p. 83.

claims in the promotion of food products, and thus to protect the public and medical profession against deception by untruthful or fraudulent health, nutritional, or other advertising claims for food." It is gratifying to learn that almost every reputable manufacturer of food products whose claims have been under scrutiny has voluntarily modified his advertising propaganda to meet the demands of the committee. "It is only the manufacturer of a speciality on the borderline between the food and drug field, whose existence depends on the promotion of a single food, who hesitates in modifying the claims that are made."

INGENIOUS DEVICES

The year's harvest of invention has been on view for the past fortnight at the Central Hall, Westminster, in the annual exhibition of the Institute of Patentees. About 400 new ideas, every one of them worked out in some visible and tangible form, prove that Mother Necessity is still fecund. The visitor has no means of knowing the names of any of the inventors; they are all anonymous, and indicated only by numbers. It would be interesting at least to know their sex, and as to that there is no guidance. It is possible that the novel form of trouser-presser is the idea of a woman, and that the improved box for carrying face powder owes its origin to a man. Tennyson makes some slighting remark about the absence of women from the inventive field, and a modern playwright makes one of his characters say that women cannot have inventive genius or they would long ago have devised something to abate the horrors of "washing up." But a number of the present devices are intended, if not to eliminate that greasy performance, at least to save much domestic drudgery. Much ingenuity has also been brought to bear upon beds, invalid and other, as though someone had suddenly realized that, as most people spend at least one-third of their lives recumbent, it is worth while making them as comfortable as possible. It may be doubted whether any position in bed except the recumbent one is really comfortable, but here are back rests to enable a person to sit up without the use of additional pillows, and other thoughtful devices for ameliorating the lot of the bed-ridden. Another inventor has thought of mitigating the unpleasant experience of being called in the morning by linking the alarm clock to the gramophone. Then there are those pieces of furniture which tumble at a touch into something else—beds which become bookcases, and chests of drawers which change into grand pianos. One little piece of combination work is a walking-stick which transforms itself into a tripod camp stool, and from that into a bathing raft. But it is the motorist for whom inventors toil hardest. What with anti-dazzle headlights, automatic car hoods operated entirely from the driving seat, unpuncturable tyres, cars which give the alarm when tampered with by an unauthorized person, signalling devices, direction indicators, motorists' caps embodying a complete inspection lamp, the motorist is well served indeed. Few of the exhibits have any medical interest, except, perhaps, an adjustable thread-tension device for eliminating the practice of shuttle-kissing—that is, sucking the weft through the eye of the shuttle—which is so dangerous to the health of the weaver.

THE B.C.G. TRIAL AT LÜBECK

In the *British Medical Journal* of June 6th we published, at page 986, an impartial review of the circumstances of the B.C.G. tragedy at Lübeck, so far as these had been brought to light, together with some discussion of the difficulties in the way of any attempt to elucidate the affair. It will be recalled that during a period of two months, from February 24th to April 25th, 1930, the B.C.G. strain of tubercle bacillus was administered to 249 newly born infants at Lübeck. Of these many developed acute tuberculosis during the next few weeks and died; others developed subacute lesions, while a considerable proportion remained perfectly well. The total death roll up to the beginning of the present year was 75. This tragic episode has again been brought into prominence by the trial which opened on October 12th before the Superior Court at Lübeck. The defendants answering to charges of criminal negligence and manslaughter are: Dr. Ernst Altstaedt, chief of the Lübeck Health Board; Professor Max Klotz, chief physician at the children's hospital; Professor George Deycke, medical superintendent of the municipal general hospital; and a nursing sister who was employed in the laboratory, Fräulein Anna Schütze. The case for the prosecution rests in the main on reports upon the material collected and examined by Professor Ludwig Lange in the laboratories of the Reich Health Office in Berlin, and on the testimony of other tuberculosis experts, who have studied the virulence of the Lübeck vaccine. Much difficulty was experienced in obtaining suitable cultures for examination, since the B.C.G. subcultures and the vaccine in Professor Deycke's laboratory had been destroyed. Needless to say, the proceedings at the trial are being followed with eager attention by the German medical profession.

INSTITUTE OF MEDICAL PSYCHOLOGY

The Tavistock Square Clinic, now in its twelfth year of work, has for several years been faced by the necessity for expansion and consequent removal from its original premises. The proposal to change its name to "The Institute of Medical Psychology" has recently been carried into effect, and the Board of Trade has sanctioned the legal alteration in title. Financial considerations have so far made the acquisition of larger premises impossible, but it is hoped that this step may be taken before long. The clinic has for the last five months been obliged to keep its waiting list closed because of the number of patients awaiting treatment; we are informed that it will, however, be reopened very shortly.

The Lord Chancellor has appointed Dr. Arthur Rotherham, now a Senior Commissioner of the Board of Control, to be a Chancery Medical Visitor of Lunatics, in succession to Sir Robert Armstrong-Jones, who has retired.

We regret to announce the death in Dublin, at the age of 88, of Sir John Hawtrey Benson, a former President of the Royal College of Physicians of Ireland, and consulting physician to the Royal City of Dublin Hospital.

NATIONAL RADIUM CENTRES

REPORT OF THE RADIUM COMMISSION

The second annual report of the Radium Commission, published this week, records its proceedings from September 1st, 1930, to August 30th, 1931. As directed by the Treasury, however, the financial statement covers the period of the financial year—April 1st, 1930, to March 31st, 1931.

During the twelve months under review the Radium Commission was constituted as follows:—*Commissioners:* Viscount Lee of Fareham (chairman), Mr. Comyns Berkeley (vice-chairman), Mr. H. L. F. Fraser, Professor G. E. Gask, Professor A. J. Hall, Dr. G. W. C. Kaye, Mr. W. Ernest Miles, Professor J. M. Woodburn Morison, Mr. Carlton Oldfield, Professor Sidney Russ, Lieut.-Colonel A. B. Smallman. Professor Russ is scientific secretary to the Commission, and Miss K. Griffiths office secretary. The office of the Commission is at 5, Adelphi Terrace, Strand, W.C.2. Ten full meetings of the Commission have been held, in addition to numerous sub-committee meetings, visits of inspection, and conferences with various outside bodies and representatives of hospitals. The report is as follows.

Summary of Progress

The year has been largely occupied in developing the National Radium Centres. In a certain number of places good work in radium therapy had already been carried on for some years before the setting up of this national system—notably in Manchester, where a Radium Institute was established in 1915, and also at Aberdeen, Birmingham, and Cardiff, which have been for several years centres under the Medical Research Council scheme of research in radium therapy. In these places there was already suitable accommodation, together with a trained and experienced staff, equipped and competent to take up and carry out the requirements of the Commission. Other places were less developed, and such radium as was already in use was not concentrated in one institution, nor was it under the control of any specially qualified staff. Indeed, at the time the Commission was set up, the number of medical men throughout the country with sufficient knowledge and experience of radium therapy to take control of a National Centre was very limited, and certainly quite inadequate. Since the Commission's scheme was launched, however, a number of qualified candidates have taken up this special branch of medicine, and, by courses of study at various centres in this and other countries, have prepared themselves for the position of radium officers.

Development of Policy of Concentration

National Radium Centres.—In accordance with its already declared policy, the Commission has systematically developed its plan of concentration of radium therapy at certain hospital centres, each of which had been nominated by the medical faculty of the local university. In thus co-operating with the Commission the medical faculties have in many cases had difficulties to surmount, especially where a selection of one out of two or three local hospitals had to be made. In one instance only has this concentration at a single hospital proved impracticable—namely, at Glasgow, where the population of the area to be served (over 2,000,000) is so large that its needs justified and demanded a departure from the original plan of a single hospital centre. The Commission therefore decided to treat Glasgow as an exceptional case, and to institute two National Centres there—one at the Western Infirmary and the other at the Royal Infirmary. This policy has received the full approval of the medical faculty of the university and of the two hospitals concerned.

Regional Radium Centres.—Owing to the uneven geographical distribution of universities with medical schools and complete clinical courses, the existence of which had determined the location of the twelve National Radium Centres, it became apparent that there were considerable areas in England which could not be adequately covered by any of them. These lacunae lie chiefly in the East Anglian and South-Western districts, and are beyond even the wide area from which the great hospitals in London necessarily draw their cases. The Commission has consequently given careful consideration to the needs of these areas, in order to determine how best to provide them with radium, whilst at the same time ensuring that the conditions under which such subsidiary centres will be administered should approximate to the same standards of efficiency as those maintained at the National (University) Centres. In pursuance of this policy the authorities of certain hospitals in each such area have been provisionally approached and asked whether they would be willing, and in a position, to provide the requisite facilities for the establishment of a Regional Radium Centre, if they should be invited by the Commission to do so. The matter is, in each case, still under consideration, and no definite arrangements have yet been made, but it is hoped that in the near future these gaps in the national organization may be filled, whilst preserving the main policy of the Commission that radium therapy should, at the present stage, be concentrated so far as possible at centres which are adequately staffed and equipped.

Rental Charges.—As stated in the Commission's first report, a rental of 2 per cent. per annum of the capital value of radium and containers loaned has been charged to centres, in order to cover the overhead expenses of the Commission without having to encroach upon the funds collected for the purchase of radium. Owing, however, to the National Centres being in various stages of development, the Commission has, during the past twelve months, received rental on only a proportion of the radium purchased by the Trust, and is therefore not yet in a position to determine whether, and if so when, any reduction in the percentage charged can properly be made.

Progress at National Centres

During the past year visits of inspection have been made by subcommittees of the Commission to each of the National Radium Centres. The main object of these visits was to obtain first-hand information as to the way in which the work of the centres was developing, and to ascertain (*a*) whether any outstanding difficulties were being experienced, (*b*) whether the centre had sufficient (or too much) radium for its needs, and (*c*) how far the centre was in a position to satisfy the requirements of the Commission in the way of carrying out the definite lines of policy laid down.

It may be said at the outset that the visiting subcommittees have been able to report to the Commission that they found in all the centres a fine spirit of co-operation in this national work and a keen desire to assist the aims of the Commission. Some centres, as already mentioned, were more advanced than others, which had had exceptional difficulties in the way of organization and of economics to solve; but even in the case of Newcastle, where abnormal conditions have prevailed, these obstacles have been largely overcome.

It is not proposed in this report to go into details of these visits, but some indication may be given of the varying stages reached in the initiation and development of the centres forming part of the national scheme. The

new organizations have had, perforce, to be fitted into the working arrangements of big hospitals (generally of 500 beds and upwards), and it says much for the spirit of adaptation in such hospitals, all of which are "voluntary," that the requisite arrangements have so successfully been made

Scottish National Centres

Aberdeen (University of)—The radium therapy department at the Royal Infirmary had been reorganized in such a way as to ensure that the closest co-operation should exist between the surgeons in charge of the patients and the radium officer, pathologist and physicist. This centre had just completed its arrangements for the formation of a radon centre, and the apparatus in charge of the physicist was then under tests preparatory to being put into use. A scheme for the organization of teaching at this centre was approaching completion. Information was obtained that there was no waiting list as cancer patients were always placed upon an emergency roster for immediate treatment.

Dundee (University of St Andrews)—It was found that no radium officer had yet been appointed at the Dundee Royal Infirmary. The visiting committee was also informed that for the last six months the number of cancer cases, both in private practice and at the hospital, had been markedly fewer than for a long time previously. This is contrary to experience elsewhere in Scotland, and the reasons are not yet clear.

Edinburgh (University of)—The new radiological block at the Royal Infirmary affords the fullest facilities for all kinds of x-ray work. The main question with which this centre has lately been concerned has been whether a new and special radium institute was necessary. One of the outstanding difficulties was that the Infirmary had not sufficient beds and in consequence it had a considerable waiting list of cancer patients. In order to relieve this position, and at the same time to give effect to the radium policy of the Commission, certain definite proposals have been approved, and are now being adopted. These may be summarized as follows: (1) Cancer patients suitable for treatment should be admitted at once; (2) while being prepared for treatment they should be accommodated outside the wards in another institution suited for this purpose; (3) the actual radium treatment should be carried out in the Infirmary wards only; (4) after treatment they should be transferred back to the associated institution for their period of early convalescence or to await further treatment for which they would be readmitted to the Infirmary if the necessity should arise. The visiting committee was also informed that efforts were being made to dissuade some of the smaller towns in the neighbourhood from starting independent schemes for radium treatment which might prejudice the policy of concentration of such work in Scotland.

Glasgow (University of)—The single centre originally nominated by the medical faculty had been established at the Western Infirmary, and a radium officer had been appointed to organize the work. It was ascertained, however, that, whilst under this arrangement the approved allocation of two grams could not be fully utilized, there were a number of patients waiting for treatment for whom accommodation could not be provided. Subsequently, as mentioned above, the Commission decided that a second National Radium Centre should be formed at the Royal Infirmary.

Welsh National Centre

Cardiff (University of Wales) is the centre for Wales, and a visit to the nominated institution (the Royal Infirmary) showed that its organization was making good progress, and had been strengthened by the appointment of a radium registrar. At this centre the radium therapy is under the control of a radium committee which consists of members of the Medical College and of the staff of the Royal Infirmary. The radium registrar sees all the cancer patients, has entry to the cancer wards, and attends all operations upon such patients.

English National Centres

In England there are eight such centres, including Mount Vernon Hospital and the Radium Institute, London, which latter are looked upon as one centre, and recognized as a post-graduate school for the whole country.

Birmingham (University of)—There has been a Medical Research Council centre at the General Hospital since 1921, and here again an organization has existed for some years to cope with the special requirements of the work. Recently this National Centre has been equipped with a radon installation which has been placed under the charge of the professor of physics at the university. This plant had recently been assembled, and at the time of the subcommittee's visit was undergoing preliminary tests. The subcommittee was informed that £1,200 had been collected for the purpose of building and equipping the hut in which the radium was stored and the process of purification carried out. This National Centre had been in touch with no fewer than seventeen hospitals in the three counties of Warwickshire, Staffordshire and Worcestershire, all of which had sent in applications for radium supplies. It had been suggested that the basis of recognition of any of these hospitals should be that at least one member of the staff should have had experience in radium treatment and a course had been arranged at the General Hospital for the necessary instruction to be given. Here again it was learnt from the hospital organization that they were doing their utmost to carry out the policy of the Commission with regard to concentration.

Bristol (University of)—The organization at this centre has been mainly the work of Mr. Hey Groves, who, in addition to being professor of surgery in the university, is also one of the surgeons on the staff of the Bristol General Hospital. Although the clinical work of the centre is concentrated at the Royal Infirmary, there has been the fullest co-operation between its staff and that of the General Hospital, the honorary visiting staff being composed of eight members drawn jointly from the two institutions. A whole-time radium officer has also been appointed, and is consulted in all cases in which radium treatment is advised both as to methods and to dosage. Three wards have been set aside at the Royal Infirmary for radium patients. The visiting committee formed a favourable impression of the organization at this centre. Not the least gratifying feature is the knowledge that the policy of the Commission has brought about a closer understanding between the two large hospitals, and facilitated the co-ordination of their activities.

Leeds (University of)—Here an entirely new radium department has been organized at the General Infirmary, and a whole-time radium officer has been appointed. This centre has obligations not only to the Commission, but also to the Yorkshire Council of the British Empire Cancer Campaign which is actively supporting it by the loan of radium and by sharing to some extent in the expenses of the new department. It draws patients from a large and densely populated area, and is faced with a shortage of bed accommodation, especially for women patients suffering from malignant disease. Efforts are being made to cope with this deficiency.

Liverpool (University of)—Here the treatment of cancer patients with radium has had to be entirely organized at the Royal Infirmary, but in the comparatively short time that has elapsed since this work has been taken in hand good results have been achieved. As at other centres the pressure on the available bed accommodation is a serious factor and although twenty-four beds are at present allocated to the treatment of cancer patients by radium, this number is not sufficient to accommodate all those awaiting treatment. Plans were being discussed to deal with this situation.

Manchester (Victoria University)—There has been a radium institute associated with the work of the Royal Infirmary since 1915, and there is no need to refer to the excellent work which has been systematically pursued there since.

Newcastle (University of Durham)—At this centre arrangements for the development of radium therapy at the Royal Victoria Infirmary, Newcastle-upon-Tyne, are still in the initial stages, largely owing to the difficulty of raising funds. It is, however, expected that financial support from the British Empire Cancer Campaign may enable this centre soon to play its proper part in the national organization. A scheme has already been approved under which £15,000 will be provided by the North of England Council of the British Empire Cancer Campaign, on condition that the Royal Victoria Infirmary will provide £5,000. This total sum of £20,000 will be spent over a period of seven years, and is designed to cover the structural works necessary and the expenditure on new permanent members of staff qualified to carry on a radium centre on approved lines. The Cancer Campaign has also agreed that the balance (£10,000) of the £25,000 which it is

expected the fund will ultimately reach shall be devoted to local research work. The work of the local Radium Institute, and the administration of the research fund, will be under the joint control of a committee representing the University of Durham College of Medicine, Royal Victoria Infirmary, and the North of England Council of the British Empire Cancer Campaign.

Sheffield (University of).—Although a considerable amount of radium work has been done at this centre, the increased work entailed by the acquisition of the national radium has necessitated some reorganization and the appointment of a radium officer. It was apparent that the successful solution of the problem of concentrating the radium therapy at the Royal Infirmary was largely due to the good will shown by two other large hospitals—namely, the Sheffield Royal Hospital and the Jessop Hospital for Women—and the radium officer of the centre is now in charge of the radium at both of these institutions.

Radium Supply

The total amount of radium ordered, or approved to be ordered, by the Trust now amounts to 24.9 grams. The total amount delivered by the supplying company (up to August 31st, 1931) amounts to 21.8 grams. Of this total about 20.7 grams have been already allocated, and about 17 grams actually delivered to centres. This last figure is not quite so high as was estimated in the Commission's previous report, but, owing chiefly to present financial conditions, at least three National Centres (Mount Vernon Hospital, Edinburgh, and Newcastle) have been unable to take up the full amount of radium originally asked for and allocated to them, whilst three centres (Bristol, Liverpool, Newcastle) are not yet ready to take over the supplies of radium allocated to them for the purpose of their radon installations. With the foregoing exceptions, the amount of radium actually in use at centres is well up to anticipation.

National Post-Graduate School of Radiotherapy

Mount Vernon Hospital (Northwood) and the Radium Institute, London.—Several visits of members of the Commission have been made to this centre during the period under review, and it is gratifying to record the spirit in which the proposal for this joint school has been accepted by both institutions and brought to what must be considered a satisfactory stage. Already two courses for post-graduate students have been organized and carried through. On the other hand, it must not be supposed that attendance at these courses, which are necessarily short in duration, can give the surgeon, or even the surgeon-radiologist, sufficient knowledge and experience to enable him efficiently to practise radium therapy without the advice and assistance that he should receive from a specialist radium officer of the kind referred to below. A third course is being held this month, and it has also been arranged that some of the lectures in connexion with the Cambridge Diploma in Medical Radiology and Electrology shall be given at the school. The actual treatment of cancer patients is carried out on similar lines at the two institutions, and there is a close co-operation between them upon all aspects of the subject—namely, clinical treatment of patients, teaching, and research. It is also worthy of note that this post-graduate school has, on the research side of its work, received the support of the Medical Research Council and of the British Empire Cancer Campaign. It is, however, very regrettable that the work of all kinds—clinical, teaching, and research—at Mount Vernon Hospital is at present greatly hampered by lack of funds. Indeed, out of a total of 150 beds only 70 can at present be used owing to financial stringency.

National Radon Centre, Radium Institute, London.—As previously stated, the Radium Institute has undertaken to produce national radon, from radium loaned for this purpose by the Commission, for the benefit of such National Centres and other institutions as are prepared to observe certain conditions with regard to its use. Such radon will be supplied at a uniform flat rate of one shilling per millicurie for the use of non-paying patients. The main conditions are: (1) the applications for national radon must come from an institution, and not from an individual; (2) the institution must be able to satisfy the authorities at the Radon Centre that its staff is sufficiently experienced in the use of radon; and (3) the staff of the institution must be prepared to keep records of cases (including "follow-up") on the radium national forms and to furnish to the Commission a summary of the results on prescribed forms at the end of each period of twelve months. (Specimens of all such forms can be obtained from the offices of the Commission, 5, Adelphi Terrace, W.C.2.)

The Four-Gram "Bomb"

In the first report of the Commission [summarized in the *Journal* of October 18th, 1930, p. 656], it was announced that the bomb loaned to the Westminster Hospital had been definitely assigned to the task of trying out the methods of deep radium therapy, or mass irradiation, in cases of malignant disease which, owing to their situation or their inaccessibility, were unsuitable for other treatment. At that time the available information as to the value of deep radium therapy in this type of case was by no means extensive or convincing. Moreover, from the few centres in other countries in which this form of treatment had been carried out, exact records of the results were difficult to obtain, and such as were available showed so many variable factors, as regards both the type of cases dealt with and the combination with other forms of treatment, that it was not possible for the Commission to form any clear estimate of its clinical value. Some authorities spoke favourably of it, others had tried and abandoned it. In allocating the bomb to Westminster Hospital, therefore, it was stipulated by the Commission that its trial should be strictly limited in scope, and that preference should be given to cases of malignant disease in three regions only—that is, breast, stomach, and prostate—in connexion with the two latter of which, at any rate, the ordinary methods of surface therapy had hitherto proved inefficacious. These conditions have been loyally observed by the Westminster Hospital, but the results, over a period of more than a year, clearly confirm—what has also been the experience abroad—that this form of radium therapy, under present conditions of knowledge, cannot be recommended for treatment of cancer in these regions. Nor, at the Westminster Hospital, were any better results obtained in the few cases of deep-seated cancer of other organs in which this method was tried. It was therefore felt by the Commission that the continued use of the four-gram bomb in its present form was not only uneconomic but unwarranted. This whole subject of surface therapy by means of radium bombs is one which is only very partially explored, and the Commission, in conjunction with King Edward's Hospital Fund for London, is at present engaged in considering what the policy for the future should be. The Commission is aware that in some centres abroad—notably in Paris, Stockholm, and New York—more favourable views prevail as to the merits and possibilities of bomb treatment in certain regions of the body, and authoritative statistics on this subject will be awaited with interest.

Radium for Research

Under the terms of its Charter, the Commission has two main obligations imposed upon it in administering the national radium, and, whilst it has considered that its most pressing duty is to "promote the treatment of

the sick throughout Great Britain," it has also taken steps to forward the "advancement of knowledge of the best methods of rendering such treatment." With this latter object in view it has allocated one gram of radium element to the Medical Research Council and 0.18 gram to the National Physical Laboratory. The policy of making such allocations to large corporate bodies which are in touch with individuals specially qualified to conduct the kinds of research work involved seems to offer many advantages, and the Commission is confident that the radium will thus be used to the best advantage. It is an encouraging sign of the activity of experimental research in radium that, within a few months of completing the arrangements with the Medical Research Council, ninety-five per cent. of the loaned gram had been allocated to research groups.

Care and Custody of Radium

The Commission has from the first laid great stress upon adequate precautions for the safe custody of the national radium, and upon the observance of the most rigid care in its use, and has issued memoranda to all the centres enjoining their adherence to certain prescribed rules.

In a few cases insufficient care has been taken, and small quantities of radium have been lost. This is regrettable, and suitable action has been taken, but a far more serious consequence, in one or two isolated instances, has been unnecessary injury to the health of the individual charged with the duty of handling the radium. In the special instances noted two not uncommon causes may have contributed to the unfortunate result. On the one hand, the keenness on his work of a radium officer may lead him to neglect some of the necessary precautions designed for his own safety, and he may not become conscious of the injury to his health before it is well established. Moreover, even when periodic blood tests have been made, the results of such tests have not in all cases been adjudicated by those who are competent to judge their significance, particularly in the early stages, and it is the view of the Commission that for the protection of the personnel the reports of the periodic blood counts made at regular intervals (at least twice a year) should be submitted to one of the physicians of the hospital concerned, who should be appointed by the board of management to have medical charge of the radium staff.

On the other hand, there are the perennial difficulties of hospital finance. Radium officers are expensive, and sometimes unforeseen, additions to the staff. Moreover, they require exceptional periods of rest, which means that they must have substitutes capable of carrying on their work. This is not always easy to arrange, financially or otherwise, and radium officers, being usually young and keen, either minimize the risk to which they are exposed, or, knowing the financial difficulties, hesitate to make representations on their own behalf. The Commission feels a special concern with regard to this matter because it has good reason to believe that routine work with radium should involve no real risk to operators, provided that the accepted precautions are strictly observed by all concerned—including the hospital boards.

Radium Officers

This whole question of radium officers, so vital to the efficient working of the National Radium Centres, presents great difficulties—particularly in the present condition of voluntary hospital finance. In some quarters it would seem that the importance and proper functions of a radium officer are imperfectly appreciated, and even when the necessity of such an appointment has been recognized, the special training required is apt to be rated unduly low. For example, it has sometimes been thought that any young doctor who has paid a flying visit to the chief radium centres—at home or abroad—could thereby acquire sufficient knowledge and experience, not only to take charge of large quantities of radium, but also to advise surgeons with regard to its clinical use. This is a large and risky assumption, and one which would not be for a moment endorsed by leading radiologists. The most authoritative opinion is now inclined to lay down that, in order to become a radium officer in the full acceptance of the term, it is desirable that an otherwise qualified candidate should be trained at a recognized centre, under skilled radiologists, for a period of not less than twelve months. To satisfy this ideal requirement would, of course, entail the acceptance of an additional financial burden which it might be increasingly difficult for new or potential centres to contemplate, and yet it must be of vital importance, both to the Commission and to the public, that the national radium should be utilized only under the best conditions—so far as it is humanly possible to provide them.

Clinical Records and Summary Cards

The forms of clinical record drawn up by the Commission, in consultation with members of the Radiology Committee of the Medical Research Council and British Empire Cancer Campaign, and of King Edward's Hospital Fund for London, are now being used by all National Centres, and have also been adopted by other institutions, both in this country and elsewhere. The Commission attaches the greatest importance to the accurate keeping of these records, which should, at the end of five years, provide full and uniform details of a very large number of cases upon which some definite conclusions as to the value of radium therapy may properly be based by competent authorities. Visiting committees of the Commission were very gratified to find that in all centres care was being taken that the records should be properly kept and filed. In consultation with Professor Major Greenwood, the Commission has now drawn up statistical summary cards which have been issued to all centres. Each case of malignant disease treated with radium will be summarized on one of these cards, which will be returned to the Commission once yearly for the compilation of national statistics on a scale which has never before been available in this country.

The Commission nominated Mr. Comyns Berkeley as its representative at the third International Congress of Radiology, which took place in Paris from July 26th to 31st, 1931.

Conclusion

In its first report the Commission emphasized the importance of caution in estimating the value of radium in the treatment of malignant disease, and the danger of creating hopes, the realization of which, in the present state of knowledge, can hardly be anticipated. The Commission can base its judgements only upon ascertained facts, which alone provide a foundation for any real scientific progress in the therapeutic use of radium. At the same time the unwillingness of the Commission to adopt optimistic conclusions must not be misunderstood, and its present opinion may fairly be summarized as one of hopeful expectancy. It realizes to the full the excellent results which radium therapy often achieves in cases of malignant disease affecting certain regions of the body—in particular, the uterus, the breast, the mouth, and the skin. Moreover, even in those cases in which permanent cure cannot be reasonably expected, the amount of pain and distress which can be alleviated by the use of radium makes the treatment well worth while. On the other hand, cancer affecting other organs has not reacted to radium treatment with correspondingly happy

results, and the Commission's note of caution was specially intended to emphasize the danger of generalizing from success in a few areas of the body to success in every part thereof.

The great need at the present time is reliable information with regard to the value of radium as a method of treatment, when practised by those who have the necessary knowledge to use it properly. Time, and a sufficient volume of accurate and uniform records, are essential to the solution of this problem, and, as the Commission has already indicated, a period of five years at least from the inception of the national scheme will be necessary before any confident verdict can be given.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY

The annual general meeting of the Medical Sickness, Annuity, and Life Assurance Society, Ltd., was held at the First Avenue Hotel, High Holborn, W.C., on October 7th, when Dr. F. C. Martley, chairman of the board of directors, presided.

Chairman's Address

Dr. Martley said that in spite of the present financial position of the country the society's business had progressed smoothly. The fact that the premium income of the Sickness Fund exceeded the previous year's by some £6,000, making a total of £72,000, proved that the society was in a thoroughly virile state. Though the increase of numbers at risk had raised the sum of sick pay to be provided and an increase in the total disbursed during the year, the amount was well within the expectation. The business in connexion with the life assurance fund continued to show a satisfactory increase now that people were beginning to realize more and more the value of life assurance as an investment, apart from its value as protection to dependants against disaster. In cases where it was not possible to pay the whole premium in one sum the society had arranged to receive monthly instalments, a concession much appreciated by members. The practice-purchase scheme, started for the purpose of assisting young men entering on their careers with the necessary money for the purchase of a practice or a share in a partnership, was progressing favourably, and no bad debts had been incurred. In fact, during the past year several members had repaid the whole sums borrowed earlier than was required under their agreements. The house-purchase scheme had also proved a great success, and the hopes expressed last year of the expansion of this business had been realized. By rigid economy they had been able to show a slight reduction in the administration expenses. As the business extended it had been found necessary to provide the manager, Mr. Sutton, with an assistant. The investments were constantly under review by the directors, and everything possible was done to ensure the safety of the society's funds. In spite of the depreciation in some of the stocks, others had appreciated so much that in the aggregate the society's investments marked at the prices on June 30th were £9,561 in excess of those prices, without taking into account the reserve fund of £9,000. The sickness and life funds had increased by £80,973, and the total funds were £766,607.

Acting on the advice of the actuary, the directors were again able to propose the payment of an interim bonus on all with-profit policies for permanent sickness and accident insurance and life assurance becoming claims during the year July 1st, 1931 to June 30th, 1932. Inasmuch as the financial situation had changed completely since June 30th, and in view of the society's quinquennial valuation in June next, the directors had carefully considered future policy as regards bonus, and their ideas had been summarized in a statement issued by one of the leading British insurance offices, pointing out that in the event of a financial catastrophe it might be necessary to suspend temporarily the declaration of bonus. It was hoped that by the time the society's valuation came along the position would be clearer; he considered it only fair, however, to point out to members what steps might have to be taken. The depreciation of securities was, in the main, artificial, since there was no question of their intrinsic value; apart from such depreciation, the society was in a most flourishing state; the new business since the beginning of July was well in excess of that in the corresponding period of last year. In concluding his address Dr. Martley paid tribute to the loyalty and efficiency of the whole staff, and added a special word of praise to Mr. Sutton.

The annual report for the year ended June 30th, 1931, was adopted unanimously. Dr. F. C. Martley and Mr. R. J. McNeill Love were unanimously re-elected to the board of directors, and Messrs. Harber, Sturges, and Fraser were reappointed auditors.

The recommendation was unanimously approved for the payment of an interim bonus on all with-profit policies for permanent sickness and accident insurance and life assurance becoming claims during the year July 1st, 1931, to June 30th, 1932.

MOTOR CARS FOR 1932

THE OLYMPIA SHOW

[From our Motoring Correspondent]

(Continued from page 674)

An inspection of the cars now on view at Olympia confirms the general summary of the present trends in the motor industry outlined in this column last week. There is no question that the 1931 Exhibition will go down in history as the Show of "economy" cars. This is evidenced not only by the large number of vehicles of from 7 to 10 h.p., but also by the fact that several manufacturers hitherto chiefly associated with cars of high power are on this occasion giving greater prominence to lower-powered vehicles. Thus, at the Rolls-Royce stand a 20–25 h.p. model, as well as the older 40–50 h.p., is shown; at that of the Daimler Company special attention is being drawn to a 16–20 h.p. car; while the Lanchester Company, hitherto building powerful eight-cylinder vehicles, has now introduced a light six-cylinder car of 15–18 h.p. This tendency to cars of lower horse-power is also well indicated by a recent return issued by the Ministry of Transport, which shows that of the vehicles being sold to-day about 36 per cent. are of from 7 to 10 h.p. (R.A.C. taxation rating), 38 per cent. between 11 and 15 h.p., and 17 per cent. between 16 and 20 h.p., only 9 per cent. being over 20 h.p. Put another way, 74 per cent. of present-day cars pay an annual tax of not more than £15.

Car Prices as Low as £89

The year 1931 will also stand out as marking the fulfilment of a long-established expectation—that of the production of a practicable little four-cylinder car to sell at the round figure of £100, this being the Morris Minor two-seater, which, although introduced early in the year, makes its first appearance at Olympia. Another notable production in the ultra-cheap car line is the Rover Company's 7 h.p. Scarab, which, with a rear-mounted two-cylinder air-cooled engine, is to be sold as a four-seater at the low figure of £89. The Jowett continues to be the only other car fitted with a two-cylinder engine, while the Trojan stands alone as the user of a two-stroke motor, which, moreover, is mounted at the rear of the chassis. Another interesting feature is the choice several manufacturers are now giving purchasers of two sizes of engine (and consequently two rates of annual tax) for the same model of car. Thus, as two examples, those

who favour the Morris Cowley may have an engine rated at either 11.9 h.p. (£12 tax) or one of 14-32 h.p. (£14), while the six-cylinder Hillman Wizard is available with either 15.7 h.p. or 20.9 h.p. engine.

Changes in Mechanical Details

It is now possible to deal at greater length with some of the tendencies in the mechanical details of chassis. Following its usual plan, the *Autocar* has devoted one of its Show numbers to a buyer's guide to the British and foreign cars on the market in this country, accompanying it with an interesting analysis of chassis characteristics. From this it would appear that the writer's reference to the increasing popularity of cars with four-cylinder engines is not quite correct, for, according to our contemporary, cars with six or more cylinders have advanced from 77 to 78.3 per cent., while those with four-cylinder engines have declined from 23 to 21.7 per cent. It may be pointed out, however, that the percentages relate not to the number of cars on the road, but to that of the individual models now being manufactured. When actual numbers are taken into consideration it will be found that "fours" will next year most likely be in the majority, and, in any case, will run the "sixes" a very close race. Another interesting detail brought out by the analysis referred to above is that engines with overhead valves are the most popular type, and are steadily gaining over those with valves at the sides of the cylinders.

Mention was made last year of one striking change that has for some time been taking place in motor engineering practice—that of substituting coil-and-distributor ignition for the long-used and reliable magneto, the necessary current being drawn from the battery of accumulators now provided on all cars in connexion with the engine-starting and lighting equipment. The writer has previously expressed his views on this matter of ignition, but no good purpose can be served by offering any further resistance to the modern form, which must have proved itself reliable in view of the fact that it is now found on 80.2 per cent. of cars as against only 67.5 per cent. last year, magnetos having fallen in the interim from 25.2 to 14.5 per cent. A further indication of the reliability of the modern ignition is indicated by a greater tendency to rely on it entirely, for, while a year ago 7.3 per cent. of cars, to ensure certainty of ignition, were provided with dual methods of furnishing the spark, the proportion has now fallen to 5.3 per cent. Despite this, it may not be amiss to give a reminder of the need for regular inspection of the accumulators in order that, owing to lack of charge, or of acid, or to sulphation of the plates and terminals, they may not fail at a critical moment.

Another change in motor constructional practice is that of locating the petrol tank at the rear of the chassis and transferring the fuel therefrom to the carburettor, either by means of a small pump or by a vacuum tank, this change being noticeable on many of the small cars as well as on the larger. Thus, from 80 per cent. during the past year rear petrol tanks have jumped to 85 per cent., with a corresponding fall in the engine scuttle variety.

Central Control and Four-speed Popularity

On the transmission side of the chassis the analysis confirms the statement already made that four-speed gearboxes are rapidly taking the place of those with only three speeds, the former being this year found on 64 per cent. of cars as compared with only 55 per cent. during the past season. Gearbox control is also definitely veering in the direction of the centrally located lever, the proportion of cars so fitted having progressed from 71.5 to 75 per cent. When they were first introduced there were many who thought that gear-changing by the left hand would present some difficulty, but this has proved not to be the case. Not only so, but the fact that it enables the driver to reach, and dismount from, his seat without disturbing a passenger is proving just one of those little points that add to the comfort and convenience of motoring.

Similarly as to road wheels, the wire type has advanced in popularity from 66 to 74 per cent.; the steel disk variety, although occupying second position, has fallen from 15.75 to 13.2 per cent., while the once universally used wood artillery wheel is practically no longer found on British cars, the 1.75 per cent. with which it is credited being due to its continued employment on certain American cars. Four-wheel brakes are now standard practice, and it is to be noticed that hydraulically or vacuum-operated brakes are no longer confined to large cars, but have been adopted on some of the smaller vehicles.

Some Comments on Accessories

Apart from the large number standardized on the majority of modern cars, accessory fittings have always been an attractive feature of the exhibition; and, as there are nearly three hundred stands in this section, it goes without saying that there is no lack of variety and type. Recent legislation and orders regarding noise, thief-proof locks, and prevention of fire—it still does not appear to be generally known that all private garages are now required by law to be provided with either a fire extinguisher or a supply of sand—have resulted in the introduction of many new accessories.

There are also improvements in side windows for traffic-signalling purposes. In this connexion it seems strange that direction indicators, of which there are many varieties on the market, do not appear to have achieved any marked degree of popularity in this country, whereas in Germany and in many Continental countries they are now in practically universal use. When one reflects on the matter, it seems strange that British motorists should continue to rely on putting out their hand through the window to give following drivers an indication at a time when it is possible to do this by a device only needing the movement of a small lever on the steering column. Not only is the sticking out of one's hands an inconvenience, particularly in bad weather, but at night it often proves ineffective, while an indication of an intended turn to the left cannot be given unless there is a passenger at the side of the driver. Although not yet in sight, the time must come when direction indicators on both sides of a car will be deemed a necessary adjunct of all British vehicles. Although the demonstration held by the Royal Automobile Club at Cambridge during September last showed that the dazzle problem has not yet been completely solved, there is a growing use of dipping headlights and of full- and dim-light bulbs, while spotlights to assist driving at night, and particularly in misty and foggy weather, are finding increasing favour.

The "Servicing" of Motor Cars

Additional evidence of the endeavours of the motor industry to facilitate the use of cars is manifest by the development of the Service and Garage Equipment Section of the exhibition, in which will be found a wide variety of tools and mechanical devices for enabling garages and service stations quickly and efficiently to meet the requirements of car users. Flat rates for such periodical needs as washing and oiling, engine decarbonizing, tyre inflation, and brake testing and adjusting, etc., are increasing in vogue, and medical motorists visiting this part of the Show will realize how great is the part now being played by "servicing" in all that concerns easy car maintenance and the reduction of repair bills.

Cars for Medical Men

With so many makes and models of cars on view, it is, of course, not an easy matter to pick out those which may be said to be specially suitable for the use of doctors. There are medical men, especially in these days of reduced incomes and heavier taxation, who will find one of the "baby" cars amply meet their needs. Others will require more roomy vehicles, and still others—particularly those whose practice lies in hilly districts—more powerful vehicles. It is noticeable that more and more makers are taking up the construction of the "baby" car, for, in addition to the Austin Seven, the Morris Minor, and the Singer Junior, there are now a Standard Little Nine and

the 10 h p Hillman Minx, the prices of which, for a four seated saloon, range from £152 10s to £155 One of the surprises of the season is the production by the Crossley Company of a 10 h p car, which, as may be gathered from the fact that its price is £265, has been introduced not with the object of competing with the popular priced vehicles, but of providing a small edition of the more powerful Crossley six-cylinder cars

The Armstrong Siddeley and Austin Cars

Judging from the writer's experience, however, it would seem that the majority of doctors are to day covering their motor requirements by either a four- or six cylinder car of a maximum of 16 h p , hence, it is proposed to review briefly some of the more noteworthy vehicles which fall into this category Taking them roughly in alphabetical order, the first to be mentioned are the productions of the Armstrong Siddeley Company, which is continuing to build four models of six cylinder cars—12 h p , 15 h p , 20 h p and 30 h p This concern has for some years been equipping some of its vehicles with a special form of pre selective, self changing, four speed gearbox, which dispenses with the usual form of change speed lever It is interesting to note that this has proved so satisfactory in actual use that the makers have now decided to adopt it as the standard practice on all their different models It may be added that the 12 h p car is now being produced in two types—one with four speed gear box and V shaped radiator, and one, known as the Economy model, which differs in that it has only three speeds and has a flat fronted radiator, and which in saloon form is offered at the attractive price of £260, or £5 more if provided with a sunshine roof

For many years past the Austin Motor Company, Limited, has made a practice of adhering to a set programme of models—7 h p and 12 h p four cylinder, and 16 h p and 20 h p six cylinder—introducing improvements only as and when they are found possible, and not merely at show time A somewhat unexpected departure was, however, made by the Austin Company early in 1931 by the introduction of a light six cylinder car, known as the Harley " Twelve Six, to sell at the low figure of £193 Although the new car, which, while called a " Twelve," is subject to an annual tax of £14, immediately achieved great popularity, it is making its first appearance at Olympia at the present Show In standard saloon form its price is unchanged, but a new *de luxe* type, with leather or moquette upholstery and with sunshine roof, listed at £225, has been added to the range As regards the other sizes of cars, various detailed improvements have been introduced, despite which it has been found possible to reduce the prices slightly Notwithstanding the attention which the ' Twelve Six " has attracted, it is worthy of note that its reputation for reliability and long service remains such as to warrant the continued production of the 12 h p four cylinder car, and this in spite of the fact that its price is at least £63 more than its newer stable companion The Austin Six Sixteen—a favourite with many medical men—has also been considerably reduced in price as well as provided with a wider choice of bodywork

Cars from Coventry

Just as it was for many years the hub of the British cycle trade, Coventry may be regarded as the centre of the motor industry, responsible as it is for the production of quite a number of well known cars, including the Armstrong Siddeley, Daimler, Hillman, Humber, Riley, Rover, Singer and Standard At the stand of the Hillman Company is to be seen a car which since its introduction early in 1931 has become very popular This is the Wizard, as has already been mentioned, which is available at the same price of £270 for the saloon, with either a 15 7 h p or 20 9 h p six cylinder engine The centre of attraction at the stand is, however, the new Minx 10 h p four cylinder vehicle, which marks the entry of the Hillman Company into the field of cars offered at a moderate price—namely, £155 for the " family " saloon and £20 more for the *de luxe* model The wheel base and track of the chassis are such as to enable a body of more roomy dimensions than usual to be fitted, so that four persons may be comfortably accommodated In their class no cars enjoy a higher reputation than those bearing the name of Humber For next year the same three models of six cylinder cars as in 1931—16/50 h p , the Snipe, and the Pullman—are being continued, with improved details and with saloons ranging in price from £425 upwards

The Riley and Singer Cars

Riley (Coventry), Limited, which has for some years concentrated on the manufacture of only two sizes of chassis—9 h p four cylinder and 16 h p six-cylinder—has built up an enviable reputation for highly efficient, reliable, and speedy cars, and although these have hitherto largely appealed to sporting motorists, it is interesting to learn from the makers that the users of their vehicles now include many of the younger members of the medical profession Of the various models of the Riley " Nine the one particularly recommended for doctors' use is the " Plus Ultra coupe—a roomy two seater with a large dickey seat at the rear The coupe top is of the drop-head type, so that in fine weather the car may be used as an open vehicle Various improvements have been effected in the chassis, which is fitted with a silent third " gearbox Special features which will appeal to doctors are the provision of Yale locks to the two cubby-holes in the dash, and to a large locker at the rear, which latter may also be reached from the interior of the car, so enabling any surgical instruments and supplies to be carried in safety

One of the most popular series of Coventry built cars is that of the Singer Company, whose range extends from the 8 h p four cylinder Singer Junior to an 18 h p Silent Six at prices, in saloon form, varying from £150 to £330 The model which will probably make the strongest appeal to doctors is the new ' Twelve Six, which is fitted with a six cylinder engine taxable at £13 and the saloon which with sunshine roof and leather upholstery is priced at £235 Like all the 1932 Singer vehicles, the car is fitted with a silent four speed gearbox and with an improved design of radiator

Next week it is proposed to conclude the report of the 1931 Exhibition by a brief reference to some of the other cars displayed, and also to some of the more interesting accessories in the galleries Readers may be reminded that the Show will be open daily from 10 a m to 10 p m until Saturday, October 24th, and that the charge for admission is 2s 6d on Fridays and Saturdays, and 5s up to 6 p m , and afterwards 2s 6d , on all other days

Union of South Africa

[From our Correspondent in Pretoria]

Malaria Control in the Union

After two seasons in which malaria reached epidemic proportions, the Government decided that special research was necessary in order to devise more effective measures of control Professor N H Swellengrebel of the Parasitology Department, University of Amsterdam was accordingly invited to conduct such researches during the past summer It was somewhat unfortunate that malaria particularly in the Transvaal was not only very much less prevalent than during the two previous years but actually below that of average years Nevertheless very valuable data were collected and Professor Swellengrebel, in his report to the Union Department of Public Health was able to outline a policy which if acted on ought fairly effectively to control the disease From his investigations it appears that only two of the twenty anopheline species

in the Union are of importance as vectors of malaria—namely, *A. funestus* and *A. costalis*. He urges the necessity for further research to confirm this and other matters, and to elucidate various problems. Should he prove correct, as seems extremely likely, the control of malaria is very greatly simplified, as species sanitation—that is, anti-larval control by dealing with only a few species of anophelines and neglecting all others—becomes practicable. The problem is greatly simplified by the very definite habits of the two malaria vectors. *Funestus* larvae are found only in the grassy, slightly shaded edges of hill streams. It does not occur in seepage areas along hillsides, or in the natural or artificial swamps which occur in the course of the hill streams. It is never found in standing water. The habitat of *costalis* is equally circumscribed. It is found only in sunny, vegetationless rain-water ponds kept from drying by continual replenishment by rains. Roadside puddles and hoof-marks of cattle are among its commonest breeding places. Professor Swellengrebel concludes that, as far as *funestus* and *costalis* are concerned, no malarious areas are better suited for anti-larval control by species sanitation than those in the Union. The very extensive swamps which were hitherto the despair of the sanitarian and the planter may be completely neglected. In fact, partial attempts at draining these have in the past actually made matters worse by providing conditions suitable for *costalis* breeding. Cattle made hoof-marks in the cleared mud, and in the unshaded puddles so formed *costalis* larvae flourished.

Professor Swellengrebel comes to the gratifying conclusion that in no part of the Union need malaria prevent European settlement. It is easily within the power of the settlers themselves to produce satisfactory conditions; the conditions of settlement on land obtained through Government should include an obligation to observe injunctions laid down regarding siting, general construction, and screening of houses, and control of mosquito breeding in furrows and rain-water puddles. Educated settlers have done better than the pauper classes placed on the land, because of their willingness to carry out essential hygienic measures, especially after having learnt the lesson that neglect means malaria.

Malaria is endemic in the Union in the Northern and Eastern Transvaal and in Zululand and Natal. For both these areas special malaria staffing under Government is recommended. In Natal groups of sugar estates should be organized into health committees or similar administrative units which can be held responsible and shall provide the staff for carrying out anti-malaria measures, as is done at present by villages and suburban and residential areas. Professor Swellengrebel considers that a 1/4 per cent. of the gross annual income represents the minimum amount that should be expended by a sugar estate on anti-malarial work in an ordinary normal year. A centralized medical and hospital service for the whole sugar belt is required, and also a system of medical examination of recruited native labour before engagement. A great point is made of the fact that in Zululand much of the adult population is malaria-tolerant because of continued attacks during infancy. Such adult natives are not only virtually insusceptible to malaria, but they do not harbour the infective forms of the parasite, so that they are no danger to a non-malarious community into which they may be imported. With the co-operation of the Government it is therefore recommended that the Natal sugar belt be provided with such malaria-tolerant labour. Praise is given for the present system of trained "native malaria assistants" for the native reserves, who move about giving health talks, advice as to kraal sites, initiating treatment where such is desirable, and keeping up close touch regarding malaria matters between the native population and the authorities. The continuation of this system is recommended. In the Northern Transvaal active settlement of European farmers is taking place. Here a field station for malaria control is recommended. This station is to be fitted out for research, experimental malaria control, the training of staff, and the instruction of persons indirectly taking part in malaria control, such as district surgeons, district health visitors, and school teachers in malarious areas. Steps are being taken by the Government to carry out the various recommendations made. The research station is to be established at Tzaneen by the South African Institute for Medical Research. It will be the headquarters also of the Government malaria inspector and his staff.

Possibility of Spread of Formidable Epidemic Disease by Aviation

The public health authorities have for some time been investigating the potential danger of introduction into the Union of major epidemic diseases by aircraft. The peculiar danger in this connexion is inherent in the fact that very long journeys by air can be made within the incubation period of such diseases. Thus, if no precautions are taken, a passenger in the incubation stage of one of these diseases may leave the aerodrome apparently in good health and reach a distant part of the Union before the condition manifests itself. The disease of particular importance to the Union is yellow fever, which is endemic along the north-western coast of Africa. The vector of this disease, the Stegomyia (Aëdes) mosquito, occurs throughout the Union. The danger of such mosquitos becoming infected by an imported case of the disease is therefore very real. Passengers infected before embarkation or infected at a landing place along the route would readily provide the virus if no precautions were taken. Although man is only infective to the mosquito during the first three days of illness, the rapidity of transport will neutralize this factor, and passengers might quite conceivably land in the Union while still in the incubation stage. In addition, the risk of infected mosquitos being carried from a yellow fever area into the Union must be borne in mind. Such mosquitos might infect persons in the Union, who would then be capable of infecting local Stegomyia mosquitos. The proposed route of the Imperial Airways to the Cape will pass through Egypt, Sudan, Uganda, Tanganyika, and Rhodesia, in none of which has yellow fever been reported. But passengers to the Union from endemic zones might be conveyed by the French route connecting up with the Imperial Airways at Elizabethville or elsewhere. Private and other casual flying from such areas into the Union must also be provided for. The Union Government found it necessary to press for some alterations of the draft of the proposed International Convention for the Sanitary Control of Aircraft, which has been under consideration by the Office International d'Hygiène Publique. The original draft placed sole reliance for the carrying out or enforcing of precautions on the authorities of the country of departure, and, whatever the circumstances, did not provide for a period of quarantine or detention and observation in the country of arrival. The Union is represented in the office by Colonel P. G. Stock. It is understood that, on his representations, the revised draft, which is now being prepared for consideration by the different Governments, will be suitably amended. Special safeguards will be permissible in the case of persons landing in the Union from a yellow fever area.

Scotland

William Mackenzie Medal

The William Mackenzie Medal for 1930 for original contributions to ophthalmology of outstanding merit has been awarded by the custodians, the Glasgow Eye Infirmary, on the advice of a committee representative of the University of Glasgow, the surgeons of the Glasgow Eye Infirmary, the surgeons of the Glasgow Ophthalmic Institution, and the Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow, to Mr. E. Treacher Collins, F.R.C.S. The medal will be presented at the Faculty Hall, 242, St. Vincent Street, Glasgow, on Friday, October 30th, at 8.30 p.m., when Mr. Treacher Collins is to give an address.

Glasgow Post-Graduate Courses

The winter session of the Glasgow Post-Graduate Medical Association will begin on November 4th and end on May 25th, 1932. The range of subjects at the series of clinical demonstrations on Wednesday afternoons includes medicine, surgery, obstetrics, and a number of special subjects; the fee for the course is £3 3s. A series of special lectures will be given on Tuesday afternoons at the Royal Faculty of Physicians and Surgeons, dealing with some of the practical problems of medicine in the light of recent observations and research. The lectures are free to all medical practitioners. The staff of the Glasgow Eye Infirmary has arranged special courses in ophthalmology, and facilities for the study of clinical obstetrics and ante-natal work are offered at the Royal Maternity and Women's Hospital. A course of demonstrations on diseases of the ear, nose, and throat has been arranged at the Ear, Nose, and Throat Hospital from the middle of April to the middle of May, and a course on radium therapy is offered at the Radium Institute of the Glasgow Royal Cancer Hospital. In most of the institutions taking part in the work clinical assistantships are available. Full particulars can be obtained from the secretary, Dr. James Carslaw, 9, Woodside Terrace, Glasgow, C.3.

New Edinburgh Professor

The inaugural lecture of the chair of anatomy at Edinburgh University was delivered on October 6th by Professor James Couper Brash, who has been elected to the chair of anatomy in succession to Professor Arthur Robinson, retired. Professor Sydney Smith, dean of the Faculty of Medicine, presided, and said that Professor Brash was an old Edinburgh student, who had passed successively through the faculties of arts, science, and medicine, and had now returned from Birmingham, where he had been professor for many years. Professor Brash referred to the high level to which teaching in this chair had been raised by its occupants during the nineteenth century. He said that it was now being more and more realized that the analysis of the dead body was a preliminary to the synthesis of the living body. In anatomy they should aim at a reasonable basis in their methods of instruction, remembering that an adequate knowledge of the structure of the human body was essential, some of it directly for practice, and some of it indirectly towards the understanding of other subjects. Anatomy and physiology were two aspects of the same knowledge of man's body, and interpretation gave the soul to anatomy. Some people regarded anatomy as a pure science, sufficient to itself, but the speaker thought that the anatomist, without losing sight of this scientific aspect, should remember that the justification for his existence was the application of his knowledge to the science and art of medicine. John Goodsir, amid his speculations on the geometrical basis of organic form, had had a great passion for accuracy in the measurements and observations on which he based his theories, and the speaker thought he could not do better than keep before him Goodsir's ideals.

Banff District Mental Hospital

At a meeting on September 24th, the Banff County Council appointed Dr. George Macdonald Bell medical superintendent of the county mental hospital at Ladysbridge near Banff, in succession to Mr. John Chisholm, who had been non-medical superintendent. Hitherto the hospital, which has 210 beds, has had only a visiting medical officer. Dr. Bell is 31 years of age, and graduated M.B., Ch.B., at Edinburgh University in 1928. Till recently he has been senior medical assistant in Fife District Asylum.

England and Wales

Guild of St. Luke: Annual Service

The annual service of the Guild of St. Luke, Evangelist and Physician, will, by kind permission of the dean, be held at St. Paul's Cathedral on Sunday next, October 18th, at 3 p.m. Seats will be reserved for medical practitioners and students, all of whom are invited to attend, whether they are members of the Guild or not. Those wishing to take part in the procession should robe in the Chapel of St. Michael and St. George. The Guild of St. Luke was founded in 1864 by medical students. It was meant primarily for themselves and their fellows as a help in the special difficulties and temptations of a medical student's life. It still desires to appeal especially to medical students, but it also serves to keep before the mind of all who deal with the diseases of the body that highest part of man's nature which finds its expression in religion, its object being the mutual encouragement and support of its members in leading a Christian life. Membership of the Guild is open to students and practitioners of medicine who are communicants of the Church of England, the clergy of which are eligible for election as clerical associates. The entrance fee is 1s., and the annual subscription not less than 2s. 6d. or more than £1 1s. Tickets for the service and further particulars concerning the Guild may be obtained from the mission secretary, the Rev. S. D. Bhabha, M.D., 8, Drakefell Road, St. Catherine's Park, S.E.14.

New Radiological Pavilion at Edmonton

A new radiological pavilion, constructed and equipped on the most modern lines, was opened at the North Middlesex County Hospital on September 29th. This is the latest of several recent departures at the great Edmonton hospital, including the installation of a radium treatment centre, which we have noticed in our columns from time to time. The opening ceremony was performed by Alderman G. Marlow Reed, chairman of the Middlesex County Council, which is the authority administering the hospital. The new pavilion consists of two radiographic rooms, one of which is used also for the purpose of *x*-ray treatment, together with a power room, a dark room, a demonstration room and clinic, and the usual dressing cubicles and store accommodation. In the first radiographic room the apparatus consists of a radiographic table with tube above and below, a Gaffe-Bucky grid table for fine bone and abdominal work, and a vertical screening stand fitted with two tubes, one for barium-meal examination at a distance of thirty inches, and the other for chest teleradiography at a distance of two metres. The second room has self-rectifying tubes working at 30 milliamperes for radiography, and is provided also with apparatus for deep *x*-ray treatment, and with

tables and couches to correspond. It is claimed that the transformer in the power room is the most modern in the country; it is a 6-valve, 3-phase, 415-volt machine, fitted with relay switchgear and controls, and the high-tension current is carried through a panel in the wall to an automatic switch in the radiographic room. The dark room is equipped with two sets of thermostatic developing tanks and a drying cupboard, and is approached by a light-trap room with two doors, only one of which can be opened at a time; opposite is a plate room, where all kinds of photography and lantern slide work can be carried out. The film store is in a separate building, made of concrete and steel, and having an automatic sprinkler and alarm. Another room in the pavilion is intended for demonstrations and clinics. It has a silver screen for the cinematograph or the lantern and a balcony for the projecting instrument, and it is furnished for teaching purposes. It goes without saying that every attention has been paid to ventilation by electric fans and air ducts, the prevention of noxious fumes, and the protection of the worker by specially treated walls and doors. In fact, the pavilion, in which many Continental ideas have been incorporated, is a model of what an *x*-ray department should be. It is on a site corresponding with the principal operating theatres of the hospital, and is entirely on the ground floor. On the same occasion a nurses' home extension was opened, in the shape of a large residential block of three stories, providing, with the buildings already in existence, 210 separate bedrooms for sisters and nurses, and extensive arrangements to meet educational, recreational, and culinary requirements. Several members of the county council made brief speeches on the occasion, and prayers of dedication were said by the Bishop of Willesden.

Surgical Instrument Makers at Dinner

The annual dinner of the Surgical Instrument Manufacturers' Association took place at the Holborn Restaurant on October 9th, when Mr. Patrick C. Maw presided over a large company of members and guests. In toasting the association, Mr. H. Guy Drew sketched its fourteen years of history. It was called into being by the necessities of the war, and after the war there was some hesitation as to whether it should be continued. But the need for an organization to encourage British manufacturers, to put forward the special view of the surgical instrument maker, and to deal with post-war conditions such as dumping, the disposal of war stores, and Government and trade union interference, was soon apparent. Mr. Drew said that during its history the association had given close attention to nineteen pieces of projected legislation, and had taken part in sixteen deputations to Government Departments. Mr. Patrick C. Maw, in his reply, mentioned that during the past year an attempt had been made to defeat the wiles of some firms in circumventing the Merchandise Marks Act, and the association was able to give information to the Board of Trade whereby successful prosecutions took place in two cases. Dr. A. N. Gardner proposed the toast of "The Guests," and, in responding, Mr. T. P. Dunhill remarked on the ancient association of the instrument maker and the surgeon. Probably in prehistoric times the same individual made the implement and performed the operation, proceeding to greater refinement in the fashioning of his tool as experience taught him. Then, as time went on, one man, more skilful and sensitive than his fellows, would find his interest concentrating in the making of the tool itself rather than in the use of it. Thus, little by little, the two crafts would diverge. Some surgeons, said Mr. Dunhill, prided themselves upon the simplicity of their implements, and spoke scornfully of complicated devices. But while there was much to be said against over-elaboration, it sometimes happened that the life of a patient depended upon the availability of a complicated mechanism, and the more simple one would not suffice. The speaker added that he believed this country to be unexcelled in the making of surgical instruments, but it was well to learn everything possible from foreign nations, and then to try and go one better. He had often had occasion to admire the ingenious mechanisms which instrument makers had brought to his notice. Mr. A. Melhuish also responded to the toast, and a few further words of appreciation from the point of view of the guests were said by Mr. L. Ferris-Scott.

Correspondence

COMMON INJURIES OF THE KNEE-JOINT

Sir,—In his article on the diagnosis and treatment of common injuries of the knee-joint, in the *Journal* of October 10th, Mr. Naughton Dunn analyses the lesions found in 522 consecutive cases of injury to the knee-joint, of which 179 were diagnosed as lesions of the internal cartilage (139 being confirmed by operation), and 71 of the external cartilage (46 being confirmed by operation). The report of the proceedings of the Section of Orthopaedics at the Annual Meeting of the British Medical Association, at which the paper was read, states that practically all subsequent speakers commented on this proportion of injuries as most abnormally high. My personal experience, based upon a large series of cases, which I analyse in considerable detail in the forthcoming second edition of my book, *Internal Derangements of the Knee-Joint*, leads me, however, to agree with Mr. Naughton Dunn that the proportion of injuries to the external semilunar cartilage has previously been greatly under-estimated.

In my last personal series of 100 consecutive patients upon whom I have operated for semilunar cartilage derangement (39 hospital and 61 private patients), I found it necessary to remove the external meniscus in no fewer than 20 cases (17 in private and 3 in hospital patients). It is interesting to note that 8 of these cases were associated with a lesion of the internal semilunar cartilage, which required removal either simultaneously (2 cases), at a previous operation (5 cases), or subsequently (1 case). One case was associated with a cyst of the external semilunar cartilage, one with ruptured anterior crucial ligament, one with an osteophyte growing from the inner surface of the tibial head, and one with loose body and traumatic arthritis. Of the 20 cases, 12 were thus complicated, which seems to support the theory that lesions of the external semilunar are associated with a greater degree of violence than are lesions of the internal semilunar. It is interesting to observe in this connexion that six of my cases occurred in professional footballers, and I entirely concur with Mr. Dunn in his conclusion concerning the extremely high percentage of injuries to the external semilunar in these players. Indeed, in my last eight operations upon professional footballers for semilunar cartilage lesions, I removed a damaged external semilunar in seven!

The pathological types of lesion of the external semilunae found in my personal cases were as follows. Longitudinal fracture ("bucket-handle" type) (8 cases—complete 7, incomplete 1).—In one of these cases, a lady, there was an associated complete "bucket-handle" lesion of the internal semilunar, which I removed at the same operation. In another, a professional footballer, a "bucket-handle" lesion of the internal semilunar occurred in the same knee two years later, necessitating a second operation. He made a good recovery from the two operations, and has played regularly since. Oblique fracture (4 cases).—One of these was associated with cyst of the affected semilunar, and this specimen is now in the museum of the Royal College of Surgeons of England. Hypermobility without actual fracture (6 cases).—Of these, 5 were associated with a lesion of the internal semilunae (1 "bucket-handle" lesion and 4 hypermobile), and 1 with rupture of the anterior crucial ligament—in a

fessional footballer, who still plays regularly. Anterior end detached and hypertrophied, with loose body—1 case. Detachment of both anterior and posterior extremities—1 case.

One case, which having been operated upon by another surgeon is not included in this series, is of considerable interest. A Cambridge undergraduate was sent to me by the surgeon for an opinion upon his knee. I diagnosed that the external cartilage formed a complete disk, and this was subsequently confirmed at operation. He had had a "snapping" knee as long as he could remember, and other more recent symptoms following an injury.

I am in complete accord with Mr. Dunn in his conclusion that manipulation is rarely, if ever, of any *permanent* benefit in recurrent cases of semilunar displacement in footballers and others whose work or play is strenuous. However, as I mention in my book, *Treatment by Manipulation*, there are certain cases of this nature which do benefit, and it is certainly well worth trying when removal is refused or contraindicated for other reasons. Operative removal is, however, so satisfactory in experienced hands that it should generally be advised; but it should be remembered that this operation is delicate, and often very difficult, and is essentially one for a specialist therein. Under such conditions the proportion of complete cures should be over 90 per cent. Statistics culled from general hospitals of cases operated upon by various surgeons, often with no special experience or interest in this operation, are sometimes as depressing as they are unreliable.

I am rather puzzled by Mr. Dunn's statement: "Accurate diagnosis in many cases becomes more difficult as my experience increases." Surely every surgeon finds that, as his experience of any subject grows, his facility of accurate diagnosis correspondingly increases. If this were the general experience of orthopaedic surgeons, it would be indeed depressing, especially when one envisages the researches of recent years and the strides that the surgery of the knee-joint has made, even since the war. I cannot help thinking that this sentence as it reads (or, possibly, my interpretation of it) in some way misrepresents Mr. Dunn's real views. I note, moreover, that of his series of 522 cases, 147 (more than 25 per cent.) were "indefinite," and, presumably, undiagnosed. This very high percentage enormously exceeds the percentage of indefinite or undiagnosable cases in my own series. Perhaps this may be because Mr. Dunn demands a higher and more accurate standard of diagnosis than mine.

May I, in conclusion, thank Mr. Naughton Dunn for his lucid, helpful, and interesting paper.—I am, etc.,

London, W.1, Oct 10th. A. G. TIMBRELL FISHER.

RHEUMATOID ARTHRITIS

SIR,—The letter of "Crippled," in your issue of October 3rd, again raises a point which is of the greatest importance in the etiology of this particular type of rheumatoid arthritis. For a number of years I have pointed out on various occasions that this special type is practically confined to the female sex, that it begins about the commencement of the child-bearing period, and that usually there is a history of irregular or delayed commencement of menstruation. The disease is progressive, and is usually symmetrical and centripetal in its advance.

I am in agreement with "Crippled" that the removal of septic foci and teeth does not cure the disease, but it certainly often improves the patient's general condition, provided that the removal is performed at the most suitable moment, and that extraction of teeth is not carried out in a wholesale manner. Sepsis *per se*, I am convinced, is not the cause of the disease, and we must look for the *fons et origo* in some other direction.

In a discussion with the late Dr. Strangeways, we were both agreed that this special entity was practically confined to the female sex; that it was associated with atrophy of the muscles, which appeared along with the swelling of the affected joint, if not before; that there was local sweating of skin in joints concerned; and that the temperature was usually subnormal, though the temperature of the affected joint was raised. I have had the opportunity of watching a number of these cases during the last fifteen to twenty years, and it would appear that the disease behaves rather in the same way as disseminated sclerosis—that the primary invasion may be slight but progressive, or it may be more acute and severe; then a "halt" takes place for a period, long or short, before there is a fresh advance of the disease. These "halts" are most misleading, because if one of them coincides with some particular form of treatment one is very apt to attribute the improvement to the treatment. These cases occur among young women who lead an indoor life, especially school teachers, typists, dressmakers, and young married women. I have no recollection of seeing the disease in anyone living an outdoor life.

Further, I believe that, as in the rheumatism of childhood, we must recognize that there is a pre-arthritic debility; by turning our attention to this period of life we shall arrive at the correct etiology of this type of arthritis. I would suggest that investigation should be made along the lines of a deficiency of vitamin B and protein, and an endocrine imbalance between thyroid and internal secretion of ovary, upsetting the basic tripod of sympathetic nervous system, katabolic endocrines, and gonads. Lastly, the distinct and continued improvement of these cases by internal diathermy of the ovaries, as suggested by Cumberbatch and Robinson, quite apart from the presence of pelvic sepsis, is a strong indication that the internal secretion of the ovaries has some bearing on the production of this disease.—I am, etc.,

Harrogate, Oct 6th G. L. KERR PRINGLE.

SIR,—The much higher incidence of true rheumatoid arthritis among females than among males has been mentioned by "Crippled" in the *Journal* of October 3rd. It is an old observation, and a very interesting fact. How can it be explained? Is it possible, up to a point, to do so by the amount of "strain" to which the female is subject from early girlhood to young adult life (the age at which the disease is likely to appear) as compared with the young male? Strain, emotional or physical, but particularly the former, and often both together, is a very intimately connected precursor of rheumatoid arthritis—another well-known clinical fact. In the last case seen, the disease started a few days after the sudden death of a brother; and a serious relapse followed the unexpected death of her mother.

Thinking along these lines, if the life of the female from childhood to childbirth be compared with that of the male, we find the following obvious train of differences. At school, girls work harder and more conscientiously than boys. Their out-of-door life is, even in these days, more limited. Towards puberty the girl develops more rapidly. At puberty the emotional strain is definitely greater. If of the class which leaves school early, the girl takes a business training (typing, telephone, or other), or goes into a shop, office, or factory; this means indoor life, fatigue, and, too often, scanty meals. The boy is much more likely to find work in the open air. Then come courtship and love affairs, happy or unhappy, but always taken more seriously than by the male. Marriage taxes the emotions of the girl especially, and the more so if unhappy; after marriage circumstances are often more

straitened than before. Then pregnancy, and, with childbirth, possibly lowered health, even infection. Rapidly succeeding pregnancies (and it is to be noted that rheumatoid arthritis nearly always picks out the slender type of woman—that is to say, the most active sexually), lactation, the anxiety of bringing up a family, well or sick—all are stresses which the male does not experience. As the family grows, life is often harder and more costly, and the mother bears the chief brunt.

The result is a sum total of long-drawn-out strain—mental, emotional, physical, sympathetic, endocrinal, what you will—to which the male is in no wise subject to a comparable degree. To it some will add infection as the precipitating cause. Is it not possible that here we have the key to the problem of the sex incidence? But, after all, it goes little further than saying that women are more subject because they are females. However, if to carry it in mind helps to emphasize the factor of fatigue, depletion, and so forth, in the causation of the disease, it may help toward more timely preventive measures, and, in treatment, insistence on the all-importance of sufficient rest.—I am, etc.,

Droitwich, Oct. 10th. A. R. Neligan.

Sir,—It is generally admitted that rheumatoid arthritis is an intractable disease, and that its etiology is unknown. Even now it is difficult to differentiate it from other forms of polyarticular arthritis due to various infective organisms. Early diagnosis and treatment are so important, and yet so difficult unless one has some idea of the cause of this condition. In my opinion it is due, in part at least, to nervous shock, causing imbalance of the endocrine glands, or biochemical changes which affect the central nervous system.

It is important to take the history of these cases very carefully as to onset and early symptoms. We are often told that the patient was in perfect health and very active until she had a severe shock, such as a motor or bicycle accident, sudden death of a near relative, financial stress, or an apparently normal confinement. Sometimes, in severe cases, in less than a week there is an acute arthritis affecting the smaller joints, but rapidly spreading to the larger and stimulating an attack of acute rheumatism. The constitutional symptoms may resemble those of Graves's disease or other endocrine imbalance. The disease is progressive, and results in severe crippling and much deformity. In a typical case there is no evidence of focal infection, and treatment by vaccines is absolutely contraindicated. Rest, symptomatic treatment, and psychotherapy are very useful in early cases. The disease seems to die out in time, so that every effort should be made to keep the joints movable and in good position. Dr. Midelton of Bournemouth treated these cases with cautery of the spine, and I have found it a most useful form of treatment in early cases.

Rheumatoid arthritis is found in all classes, and affects chiefly women of child-bearing age. The difficulty of treating these cases in hospital is well known: supervision and suitable surroundings should be available until the disease is arrested. The temperament of most of these patients is characteristic. Before the illness they were usually active in mind and body, and as the condition progresses they seem to develop a certain resistiveness, which is very difficult to overcome, and which retards recovery. To be told or to read that their disease is incurable has a most adverse influence on them, and we should always try to inculcate hope and patience. Cases which appear hopeless sometimes make good recoveries.—I am, etc.,

Buxton, Oct. 6th. Florence Theobalds, M.D.Ed.,
Honorary Physician, Devonshire Hospital.

DOSAGE OF DIPHTHERIA ANTITOXIN

Sir,—In your interesting leading article of October 3rd, dealing with the dosage of diphtheria antitoxin, there is one remark which must appear to many of those engaged in the clinical observation of diphtheria to savour somewhat of heresy. It is stated that: "The clinician cannot well avoid the thought that . . . controlled laboratory experiment offers no justification for dividing the effective quantity of antitoxin into separate doses to be given at intervals." But are you not, in making such a generalization, rather exceeding your terms of reference? If the above statement means only that a large dose should be given as early as possible, then well and good; but if it is suggested that no subsequent injection can be of the slightest value, then it seems to some of us that such an inference is scarcely warranted by the available data.

In the "controlled laboratory experiments" which are quoted, a single dose of toxin—let us say q—was given at a definite instant of time t. It is easy to understand that in order to deal with this definite quantity q in the best possible manner, a suitable amount of antitoxin must be given at the earliest possible moment. But when we are dealing with a human being suffering from malignant diphtheria the state of affairs is surely rather different. In such cases toxin must be entering the blood stream in considerable amounts over a number of days. As evidence for the truth of this statement it seems to me sufficient to remark that the spread of membrane over the fauces in early cases can often be observed to continue for as long as two days after the injection of a large intravenous dose of antitoxin. Nor does your earlier remark apropos of Schick-negative carriers of virulent diphtheria bacilli—that "very little antitoxin is necessary to prevent the ingress into the circulation of further toxin"—seem to me to reduce the value of this observation. In Schick-negative carriers the process of toxin manufacture is apparently never permitted to start, whereas in a patient who presents the phenomenon of a "bull-neck" it is already in full swing. If you go to the Cotswolds you may be able to check the River Thames with a pebble, but you will be less successful at London Bridge.

It seems to me, therefore, only reasonable to suppose that it is highly desirable to *maintain* the concentration of antitoxin at a high level in the blood until all production of fresh toxin has ceased. This cannot be done by a single intravenous injection, because, as Park, I think, has shown, the concentration of antitoxin in the blood, which is maximal immediately after the injection, begins thereafter to fall off in the well-known logarithmic manner—in other words, it is excreted at a rate which is a function of its concentration. A similar relationship is expressed in Newton's law of cooling. In the circumstances many of us will still feel justified, when treating severe cases, in following up an initial intravenous dose with further injections into muscles at suitable intervals. It must, however, be conceded that there is still room for discussing the question as to what constitutes a "suitable interval."—I am, etc.,

London, S.W.17, Oct. 6th. J. B. Ellison.

DIET AND CARIES

Sir,—In a leading article on diet and caries, in the *Journal* of October 3rd, you refer to the work of Mrs. Mellanby, who was able, by adding vitamin D to the diet of children, to reduce the incidence of caries to one-third, as compared with a control group. Surely, if this proves anything, it proves that caries is not, essentially, a deficiency disease due to the lack of this particular vitamin; as otherwise the improvement should have been *much* greater—something approaching 100 per cent., allowing just for errors of administration and so forth. It was the

dramatic improvements that took place on the administration of vitamin-containing foodstuffs to vitamin-starved animals which definitely proved the theory of deficiency diseases, not just the improvement of a percentage. Every dentist recognizes the increased incidence of caries at puberty, during pregnancy, and after the acute infectious fevers, circumstances in which diet deficiencies, in this direction, cannot be causative; besides which, Professor Howe has produced caries in monkeys through starvation of vitamin C. On the other hand, Mrs. Mellanby's results show that diet, though not the important factor, is related in some way with caries.

When it is realized that the subject of nutrition is not summed up in the word diet, but includes the whole of the metabolic equation—intake of food and oxygen, in the one direction, and output of energy in all its forms in the other—and that for perfect function these two sides must balance, all the difficulties disappear. As it is impossible to build up a diet containing an excess of vitamins C and D which does not contain basic elements in plenty, and, conversely, any diet deficient in these will at the same time be deficient in basic substances, is it not possible that the balance here may have been responsible for the improvement of the teeth of these children? This would account both for the lessened incidence of the caries, and also for the fact that one-third of the children did not share in this improvement. In these latter, even the diet change was insufficient to balance the equation, it being attacked only from the one side.

I suggest that the output side of the metabolic equation must also be considered; and when we remember that the expenditure of energy includes not only that utilized in voluntary effort, physical and mental, but also the involuntary expenditure, which has been estimated as consisting of some 75 per cent. of the daily total, we see the importance of this in obtaining a balance. Further, as this involuntary expenditure is utilized in both physiological and psychological channels, in growth and development, in the digestive, respiratory, and circulatory functions, in emotional disturbances, in the defence against bacterial invasions, and in the conscious and unconscious mental conflicts, we realize that in an upset in this equation we can include all the causes of caries with which dentists are familiar.

A difficulty in balance in the one direction will bring about an excess of acids which, in neutralization, will use up basic salts required for special purposes in the body economy, but which, in these circumstances, must be done without. An upset in the opposite direction will lead to an excess of alkali, which in the absence of sufficient acid to neutralize it will need elimination; in both cases, according to biochemical laws, deleterious effects will be produced upon the dental tissues—caries or pyorrhoea, according to the direction in which the equation is disturbed. In my Cartwright prize essay of the Royal College of Surgeons I have stressed the essential antagonism of these two conditions, which needs something more than a diet deficiency to explain. In these circumstances, then, where decent hygienic conditions will not assure a balance, as in one-third of the children in Mrs. Mellanby's experiment, the matter may be rectified at the point of the common denominator—the acidosis or the alkalosis—by seeing that there exists sufficient cheap acid or base to neutralize any excess.

When it is understood that the whole matter of metabolism, as also of the reactions of the body to the emotions, and the defensive mechanism of the body, is regulated through the endocrine autonomic system, it will be seen, not only how interrelated these functions are, and how the threshold of efficiency depends upon a perfect balance of all its parts, but also why dental lesions are so commonly associated with functional disturbances elsewhere in the body, and associated in a certain definite way—for example, caries with achlorhydria (*pernicious anaemia*), pyorrhoea with hyperchlorhydria (*gastric ulcer*)—not, primarily, as cause and effect, but along lines of a *common etiology*.

All these are matters of extreme interest, which are not elucidated by a conception of dental lesions as disease entities dependent upon diet deficiencies, but are only understandable when we visualize them as parts only of a disease picture due to a fundamental upset of the endocrine autonomic system, as the basis from which imbalances of the metabolic equation arise.—I am, etc.,

F. W. BRODERICK, M.R.C.S.,
Bournemouth, Oct. 3rd. L.R.C.P., L.D.S.

BIOLOGICAL NATURE OF THE VIRUSES

SIR,—In your issue of October 3rd, under the above heading, Dr. Dale is reported to have made certain remarks which, taken together, appear self-contradictory, while some of them are, I think, rather mistaken. He admitted that we might be forced to the conclusion that some viruses were too minute in actuality to be considered as living organisms, but he hoped the alternative view of regarding them as enzymes might be avoided. Why, incidentally, he should "*hope*" this is not stated; but, in any case, I fear his hope is destined to disappointment. He said, further, that no evidence is available that any enzyme has the properties of a virus, or any virus those of an enzyme. He regards such a possible non-living virus as a toxin or stimulant, according to circumstances, being capable of transmission in either case. Yet in both cases he postulated, as the special characteristic of such an agent, the power of imposing on the "infected" cell ("affected" would perhaps be better) "an altered metabolism," which can lead "to its own reproduction" (by "its" here, I take it, the virus is meant).

Now in the first place, while some bacteriologists regard toxins as being in many respects closely analogous to enzymes, a true toxin is a specific, poisonous, metabolic substance more or less deadly to certain cells other than the type which produces it. Moreover, it does not affect the cells producing it in any way, and it certainly cannot, so far as we know, induce other cells to produce it. Further, one can hardly regard a toxin as imposing an altered mode of functioning upon a cell; it just poisons it, kills it, and that is the end. This is very different from the behaviour of most viruses. It is quite true that neither do the ordinary listed ferments, whose chemical reactions are well known, behave like viruses. There are undoubtedly, however, many more enzymes, especially concerned with cell metabolism itself, which remain still unknown. An agent, therefore, which is admittedly closely concerned with cell metabolism, even though it has the properties of a virus, is much more likely to be of the nature of an enzyme rather than of a toxin.

The bacteriolysin (bacteriophage) is one case in point. Many regard this process as of the nature of an impressed transmissible alteration in the function of the nutrition of the particular types of bacteria (the "nutritional vitiation" view of Bordet), which, in the case of the more resistant individuals, is hereditary—that is, can be passed on to subsequent generations. This would certainly seem to indicate the operation of an abnormal type of enzyme. Again, at the other extreme of the virus group, from my own work I have not the slightest doubt that the "Rickettsia" granules (which are indubitably closely associated with the virus itself) constitute nothing more than the residuum of an altered abnormal type of digestion of the blood in the louse. This, again, presupposes the existence of an abnormal ferment. And other cases could be cited.—I am, etc.,

Walton-on-Thames, Oct. 11th. H. M. WOODCOCK.

THE TERM "CONGENITAL"

SIR,—With reference to Mr. M. Melgrave's useful suggestion (October 10th, p. 681), that the above term in relationship to syphilis acquired before or at birth requires revision, may I be allowed to say that in my opinion there would still be some ambiguity about the precise meaning of the word "connatal," which he proposes to be used for cases of infection which occur at the time of birth. This word may equally well be applied to infections contracted *in utero*, since one of its dictionary meanings is "born with," whereas I believe there would be no ambiguity about the term "intra-natal," a word already in general use in connexion with other forms of obstetric injury to newborn infants.—I am, etc.,

London, W.1, Oct. 10th. ERIC PRITCHARD.

A PLEA FOR BRITISH SPAS

SIR,—One aspect of the present financial situation, of considerable special importance to the sick and to the medical profession, and of practical interest to the public generally, appears to have attracted little attention. I allude to the enormous numbers of the wealthier classes who, partly obeying the dictates of fashion and partly through ignorance and prejudice, have adopted the practice of residing abroad for cures at spas or sanatoriums, or of wintering abroad to escape the so-called rigours of the English climate. It must be confessed that in adopting this course they have often been guided by the advice of members of our own profession. It is certain that in the enormous majority of cases sojourn abroad is unnecessary, and that those who do not desert this country have rarely any reason to regret their action, but, on the other hand, are frequently much more rapidly restored to normal health and full working capacity.

Sun treatment has no specific action on tuberculous disease. In many sunny countries the incidence and virulence of tuberculosis much exceeds that of the disease in England. Continuous exposure to sunlight is, in my opinion, decidedly contraindicated in tuberculosis, and where sun treatment is required it may be administered with complete success in this country if combined with ultra-violet light from artificial sources. Anyhow, it is merely an aid to cure, and not essential for recovery.

It is a humiliating thought that foreign spas are alleged to be superior to English ones; and, even if their alleged superiority can be established, surely the remedy is not to admit defeat, but to so improve our English institutions that the stigma shall be for ever removed. The present is an admirable opportunity for effecting this improvement, but for the effort to be successful the whole-hearted sympathy and support of the medical profession is essential. The attractions of foreign spas and winter resorts are depicted so skilfully and alluringly that many are better known than those in this country, and the English doctor is often at a loss to know where similar benefits at home may be readily obtained, and with equal advantage to his patient. It is surely high time that some independent and influential medical body should undertake this task, investigate our resources, and be prepared to advise English medical men who need help in such matters. I suggest that the British Medical Association, with its unequalled means of obtaining the necessary reliable information, might proceed to do this, to the advantage of patients and public alike.

Before advising patients to go abroad for treatment, or simply for purposes of escaping from the English winter, I would appeal to my colleagues to inquire carefully whether the interests of their patients would not be at least as well served by remaining at home; but, if they are satisfied that England must be left, let them at any rate consider the claims of other parts of the Empire. The claims and advantages of the Channel Islands, Malta, the British West Indies, South Africa, and even distant New Zealand, should not be ignored. An enormous amount of British money must be lost to the country and its exchequer annually, which is needlessly enriching foreign, if friendly, rivals, and is sadly needed at home.

The present is an admirable opportunity for checking this serious and needless injury to our country, and, while placing the interests of the patient first, I do hope that an earnest endeavour will be made to ensure the best for the patient without loss to the country to which he is doubtless proud to belong, and which at a time like the present needs and should claim the help of every Englishman, be he sick or well. The patriotic and splendid example of our own Royal Family again points the way to what is a duty to us all. For obvious reasons I withhold my name, but enclose my card.—I am, etc.,

October 10th. MEDICAL SUPERINTENDENT.

INJURY AND SPORT

SIR,—Mr. Rowley Bristow's disclaimer in your issue of September 26th (p. 588) is, I think, hardly necessary if the full context of the pertinent sentences of the paragraph be taken. It is as follows:

> "Thanks to certain ingenious technical modifications introduced by Dr. Morton Smart, his apparatus produces a far more comfortable current than the unmodified faradic current. It can therefore be used at an earlier stage of recovery than its prototype. The credit for introducing *this current as a routine procedure for injuries requiring* muscle movements and re-education is chiefly due to Mr. Rowley Bristow, and the apparatus is therefore often called by his name. The Morton Smart coil, the Smart-Bristow coil, and the Bristow coil (as it will be called hereafter) are one and the same."

The words in italics have been omitted by Mr. Bristow in his quotation, and these, with the other sentences, give, I think, full credit to Dr. Morton Smart for the original invention and use of this apparatus; but some credit is certainly due to Mr. Bristow as an orthopaedic surgeon for calling for its routine employment in suitable cases.

I was present at the discussion of the Section of Electro-Therapeutics of the Royal Society of Medicine in 1923, and heard Mr. Bristow's generous disclaimer on that occasion, and was fully aware of the exact position of affairs as then recounted. Hence the careful wording of the paragraph above quoted.—I am, etc.,

London, Oct. 9th. C. B. HEALD.

EXERCISE IN DIABETES INSIPIDUS

SIR,—I am wanting to make some simple investigations into the effects of exercise on the secretion of urine in diabetes insipidus. Should any of your readers know of a boy or young male adult who has the complaint, and who at the same time is willing to come into hospital for a week for such investigations to be carried through, I should be most grateful to hear from them. Dr. T. R. Elliott has kindly offered to take such a case into his wards in University College Hospital for the period of the investigation. The patient would, of course, be relieved of travelling and other expenses.—I am, etc.,

E. B. VERNEY.

Department of Pharmacology, University College, Gower Street, W.C.1, Oct. 12th.

Obituary

R. WALLACE HENRY, B.A., M.D.

Past-Chairman of the Representative Body, British Medical Association; Consulting Ophthalmic Surgeon, Wycliffe Society, and the Leicester School for Myopes

By the passing of Dr. R. Wallace Henry, on October 10th, the medical profession loses an outstanding figure, and one whose personality and activities must be well known to a very large number of medical practitioners. Although it was obvious that Wallace Henry had been ailing during the last two or three years, he was occupied with his professional and public duties up to a week before his end, which came as the result of arterio-sclerosis, at the age of 64.

R. Wallace Henry

Robert Wallace Wesley Henry was a native of Dublin, coming of a stock which had produced many well-known Methodist ministers in successive generations. He was a student at Trinity College, Dublin, taking the B.A. degree in 1891, the M.B. and B.Ch. in 1892, and the M.D. in 1895. He was resident surgeon at the Birmingham and Midland Eye Hospital. The writer of this memoir well remembers him in 1896 in Leicester, where he had started in practice as a specialist in ophthalmology. In those days he was of a shy and retiring disposition, and it was only gradually that his colleagues began to discover his capacity and common sense. He was regular in attendance at medical meetings, a frequent contributor to the scientific discussions, and was honorary secretary of the Section of Ophthalmology when the British Medical Association held its Annual Meeting in Leicester in 1905. In this capacity he began to find himself, and, although his name does not appear on any of the local committees of that meeting, yet the writer well remembers the unobtrusive valuable services he rendered at that time.

But it was at the time when the National Insurance Bill was introduced that Henry, at a meeting of the local profession, demonstrated his powers; and the position as an outstanding personality was accorded to him in the short space of one afternoon. Ever since that day he has held the affectionate admiration of his local colleagues, for he showed such a capable grasp of the points and ramifications of the Bill, and explained them so fully and concisely, that it became clear that he was head and shoulders above all others present. For his services he was publicly given a set of silver plate when the Act became law. About this time he became honorary secretary of the Leicester and Rutland Division of the Association and also its representative in the Representative Body, holding the former post till 1930, when again he received a presentation from his colleagues, this time a portrait in oils, which was handed to him at a very largely attended dinner. The passing of the Health Insurance Bills brought medical politicians other problems to solve, and Henry was a leading spirit in a group who formed the Leicester Union of Medical Practitioners. One important section of this was a plan to take over a large existing provident dispensary from lay control and transform it into the Leicester and Leicestershire Public Medical Service, managed and financed by medical practitioners only. Henry became first chairman of this, which is still a flourishing organization, and has been a pattern which other areas have copied. In 1912 the ancient Leicester Medical Society elected Wallace Henry as its president, and the manner of holding that office further enhanced his prestige. About this time he was making his mark in the central work of the B.M.A. His practice and his local public work were both so great that he had no spare time, and he used to say that the only form of sport in which he engaged was medical politics.

Then came the war. On August 4th, 1914, Henry was rung up and told that he had been marked down to undertake the duties of registrar of the local base hospital, which carried with it the rank of major. He protested that he was no soldier (which appeared certainly true when he first got into uniform), but, throwing himself into his duties in his characteristic manner, he made such a success of the job that he was twice mentioned in dispatches, and promoted to the rank of brevet lieutenant-colonel. After the war he became more and more a force in London, although he had a large and increasing practice in Leicester, but he still found time to keep up his scientific work, even in the whirl in which he lived. Of his work in the headquarters of the Association others who have more knowledge of it must write, but still he took on more in Leicester, for he became a member of council and a warm supporter of the newly founded Leicester University College. So keen was he on this that he undertook the chairmanship of the Hostel Committee, and also endowed a prize in biology, limited to the children of medical practitioners. Even yet other objects interested him. He was president of the Leicester Literary and Philosophical Society and president of the Leicester

Personal Health Association ; he was also a keen Rotarian, being president of that for one year, and was honorary ophthalmologist to the Guild of the Crippled and the Wycliffe Society for the Blind.

In this crowded but nevertheless happy life there was little time for rest or exercise, so is there any wonder that his vascular system showed signs of giving way? Appealed to by his friends, he did cut out some of his evening meetings, but still he did too much, for he "enjoyed doing it, and really it does not fatigue me." Always fond of music, he enjoyed concerts or musical evenings at home, when he could find time for them. The features of his public life which most gained the admiration of his friends were the extraordinary facility by which he could read through a voluminous document and pick out the essential and the weak points in it ; the marvellous memory by which he could assimilate, digest, and retain its contents (the criticisms which he levelled were never purely destructive—there were always, in addition, constructive proposals) ; the tact by which he did not lose friends when opinions were sharply conflicting ; and the devotion to the medical profession, with intense loyalty to his collaborators. He was a good public speaker, for he took pains to consider what he was going to speak about, and he was particularly happy and humorous in after-dinner oratory. He is survived by Mrs. Wallace Henry and a son and daughter. The gap he leaves will indeed be difficult to fill. A. V. C.

Dr. H. B. Brackenbury, Chairman of Council writes:

One knew that for some time past Wallace Henry had not been in very good health ; nevertheless, the news of his death came as a real and severe shock. Apart from what it means to the Association, it leaves one with a sense of grievous personal loss. This makes it very difficult to write about the man. What adjectives can one most properly apply to him? Those which first spring to one's mind are, reliable, wise, kind. Always one found him willing to contribute, willing to advise, willing to help ; and always his help was greatly worth having, and his advice well worth the fullest consideration. Long ago his qualities became known to his processional colleagues in the town and county in which he carried on his practice, and, beyond the medical profession, he was trusted in a remarkable degree by those who had responsibility for local administration and who were interested in schemes for social welfare. In the central work of the British Medical Association he was indefatigable for many years, and his sterling merits, without any very striking incidents to display them, were widely appreciated by his colleagues, so that he was elected first as Deputy Chairman and then as Chairman of the Representative Body. His value to the Association in these offices was great. He spared no effort to fill them worthily, and was even meticulous in the thought and care which he devoted to preparation for the duties which he was called upon to accept and perform. Ever since, he has been ungrudging and zealous in his work for the Association, both locally and centrally, especially as a member of Council and of the Organization, Ophthalmic, and other Committees. His colleagues on the Council have long regarded him as one of the most valuable and respected of its members, and latterly his position has been such that no one has been held in more truly affectionate regard. The profession collectively and his friends individually will feel his loss more than can, at the moment, be realized.

The Treasurer, Mr. N. Bishop Harman, writes:

The news of the death of Mr. Wallace Henry will come as a shock to many of his colleagues. It was only last week that he attended the meeting of the Ophthalmic Committee. We knew he was suffering from much physical weakness, and we were filled with admiration that, despite this handicap, he was able to maintain his mental force and sound judgement at its accustomed high level.

During a busy life as an ophthalmic surgeon he managed to play many parts, and to play them as though each was the essential interest of his life. A recognition of this by his colleagues came when he was elected Chairman of the Representative Body in 1921. The trust reposed in him by the promotion to this high and responsible office was amply justified. He proved himself diligent in his attendance on the many committees of the Association through which so much of the hard labour of medical affairs is performed ; and at the great account of these activities at the yearly meeting of the Representative Body he displayed such a frank and genial disposition, and withal such a mastery of business, as marked him out as an ideal chairman.

In later years his interest in Association affairs was mainly centred in the Ophthalmic and Building Committees. He may be fairly described as the father of the Ophthalmic Committee. Certainly he was the prime mover in its formation, and its first chairman. Through his work and his early exploration of future possible developments there came the formation of the National Ophthalmic Treatment Board, which bids fair to secure the rightful place of ophthalmic medical practitioners in this branch of medicine, and to provide for the many a necessary form of medical treatment in a manner that is both economically and medically satisfactory. His interest in the success of this work led him to make considerable sacrifice both of time and of money. He refused a tempting offer of practice rather than risk jeopardizing the success of this Association scheme.

As an ophthalmic surgeon in a great industrial centre he did much to assist researches that aimed at ameliorating the lot of operatives whose occupation entailed close and continuous eye work. He carried out, at the instance of the Medical Research Council, experiments in the provision of special forms of spectacles for those workers in hosiery factories who were required to undertake the difficult and trying form of manipulation known as "linking." The results of that work have proved a boon. He also gave much attention to the effect of disease on the light sense, and the apparatus he devised for measuring this sense and its variations showed a high degree of ingenuity and practical adaptability.

The work that he began and did will not cease with him. Others will carry it on, and justify his enthusiasm for it. But we shall miss his rugged yet kindly features in the Council chamber and the committee room, and be sufferers from the loss of his shrewd judgement and wise counsel.

The Medical Secretary writes:

The Association has been hard hit recently in its central personnel. Within the last few weeks we have had the deaths of E. B. Turner and W. E. Dixon, both of whom filled a very conspicuous place in the central ranks of the Association, and now comes the death of one who was just as well known and who seems just as irreplaceable. By the fact of being Chairman of the Representative Body (an office which he held from 1921 to 1924) Wallace Henry had to take an active part in practically every committee of the Association, but, both before he took that office and since he laid it down, his work for the Association was great and invaluable. Others will speak of his work in Leicester and the Midlands, but it was that work which trained him for central activities and made him so useful here. It was largely the fact that he had trained his own men so well and had attained such a position

of influence in his own area that made him so useful at headquarters. There was hardly a practical problem that arose centrally which the Leicester men, under his guidance, had not already thought out. This was particularly the case with contract practice problems. The work of the Association on that side has been greatly influenced by the practical experience gained by Wallace Henry and his colleagues in the organization of what is undoubtedly the most successful example of a public medical service that exists in this or probably any other country.

He was secretary of his Division for nineteen years, representative with short intervals from 1909 to 1929, secretary of the Midland Branch from 1922 to 1926, president of the Midland Branch 1926–27, and chairman of the Leicester and Rutland Division in 1930. In our central work he was particularly active on the Medico Political and Organization Committees, of both of which he had been a member since 1919. In addition to being a very useful member of every committee on which he ever sat, he was certainly one of the most popular—a position attained partly by the knowledge we all had that he never spoke unless he had something useful to say, but also by his friendliness and courtesy. As Chairman of the Representative Body he was a great success, handling the difficult business very firmly, but always in a way which gave offence to nobody. He was rightly proud of the position of influence he had attained in the profession, and I shall always remember the night I spent with him on the occasion of the presentation of his portrait by his Leicester colleagues in April, 1930. I think he regarded that as the highest honour he could possibly receive, because, as he said, there is no testimony so valuable as that of the people amongst whom one lives and works. The profession in Leicester and the Midlands regarded Henry with deep affection as well as respect, and this feeling was shared, I think, by everybody who ever worked with him. I cannot refrain from saying how much he was helped and cheered by the support of his wife, who had so often to give him up to the service of his profession, even when they both knew that his health was precarious; and I feel from my knowledge of him that he would have liked to know of this little recognition of an affection and support which he valued so much.

Dr MARSHALL HAVER died at Northallerton, Yorks, on September 30th, at the age of *50, after a long illness*. He had only recently begun work at Northallerton, his previous practices having been at Driffield and Ancaster. After graduation as M.B., B.S. at Durham University in 1905, he spent some years on a cable ship, and then on a large sheep ranch in Patagonia, as medical officer, returning to England to take up private practice. He was for some years a medical officer to the Driffield Cottage Hospital, and medical officer of health for the Driffield rural district. A colleague writes: Dr. Haver will be greatly missed by those who were privileged to be associated with him, for his quiet and genial personality was loved alike by patients and friends. He leaves a widow, but no children. The sympathy of all who knew him will be extended to her and to his father and sister, who live in Sunderland.

The following well-known foreign medical men have recently died: Dr. ALDRED SCOTT WARTHIN, professor of pathology, director of the pathological laboratory, Ann Arbor, and editor of *Annals of Internal Medicine*, aged 64; Professor CONSTANT PICOT, collaborator with the late Professor D'Espine in a well-known work on diseases of children; Dr. ROBERT CLYDE LYNCH, laryngologist, of New Orleans, from a motor accident, aged 50; Dr. JOSEPH ADDISON STUCKY, formerly president of the American Academy of Ophthalmology and Oto-Laryngology, from a motor accident, aged 73; and Professor GOLOVINE, a leading ophthalmologist at Moscow.

Universities and Colleges

UNIVERSITY OF LONDON

At the meeting of the Court of the University of London held on October 7th, Lord Macmillan was unanimously re-elected chairman for the session 1931–32, and Mr. S. L. Lowry deputy chairman for the same period.

At the September matriculation examination 91 passed in the first division and 393 in the second division, while 35 took the supplementary certificate in Latin.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The next series of eight lectures and demonstrations on *tropical medicine*, which are intended for men and women who intend the medical profession proceeding to the Tropics, will be given by Lieut.-Col. G. E. F. Stammers from October 21st to 30th. These courses, in addition to providing simple rules for guidance in regard to preparation for life in the Tropics and personal hygiene, will also embrace a short account of some of the more common diseases, with advice on measures of protection against such diseases and simple methods of self-treatment. Particulars can be obtained from the secretary, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE

The following entrance scholarships have been awarded:

Senior Entrance Scholarship in Science: G. W. Hayward and A. Jones (equal). Junior Entrance Scholarship in Science: L. H. Hoffer. Entrance Scholarship in Arts: E. P. Mountford. Jeaffreson Exhibition: G. H. Darke. Shuter Scholarship in Anatomy, and Physiology: J. Smart.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examination indicated:

D.P.H.—Part II.: S. Canter, R. F. Corlett, J. Hatton, E. W. Jones, J. N. Parrington, L. G. Thomas, F. J. Welton, E. B. Whittingham.

UNIVERSITY OF GLASGOW

The following candidates have been approved at the examination indicated:

Final M.B., Ch.B.—Anne C. Muirhead, Eleanor B. Aldrich, W. S. Bell, P. Binnington, N. Burrell, M. D. Black, J. C. Burr, A. M. Brown, C. M. B. Cade, A. Cameron, R. Cameron, D. Cassie, R. M. Crain, W. N. S. Donaldson, A. T. Elder, Mabel Fisenbacher, J. B. Fleming, A. B. Fordyce, A. C. Forrester, P. K. Fraser, Janet C. B. Fre[illegible], Muriel O. Gibson, D. L. H. Hay, J. Hosgood, G. H. Johnston, R. Laird, J. Lamb, G. C. Lamond, J. Laughton, R. Livingstone, R. L. Low, R. J. Lumsden, A. Lyall, D. MacDonald, T. J. B. MacGeoghan, D. M. Mackechnie, R. B. M'Millan, J. S. M'Nair, D. W. MacNish, H. J. MacPherson, A. O. Maclodrum, R. Maxwell, T. W. Miller, W. L. Milne, G. B. Morton, H. M. Munro, H. G. Neil, H. B. Oliver, W. T. W. Paxton, A. W. Purdie, J. L. Rentoul, J. Renwick, W. A. Roxburgh, A. Russell, N. Sinclair, J. B. K. Smith, Jean G. P. Stephen, H. Stevenson, J. S. Stewart, H. Stirling, F. W. Thomas, J. S. Topping, J. B. Wallace, J. H. Wardrop, R. A. Wilson, G. Wright.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examination indicated:

First Medical—Part I. Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.

H. D. Clarke (passed on high marks), F. A. Smyth, A. G. Tuckey, J. B. H. M'J. Horgan, J. A. Lavery, F. C. Roulette, D. G. Wilson, Ethel S. Wilson, Una M. Irwin, E. W. McCutcheon, W. A. Clarke, T. J. M'Gegg.

PHARMACEUTICAL SOCIETY

The Hanbury gold medal of the Pharmaceutical Society of Great Britain has this year been conferred upon Dr. Hermann Thoms of Berlin for his services to the science of pharmacy, and the Perera medal to Mr. H. G. Rolfe. The Jones Prize scholarship has been awarded to Mr. F. E. Read, and the winners of the three Leverhulme scholarships were Messrs. P. Crease, H. W. Bartlett, and J. J. C. Gage.

A special course of lectures on [illegible] will be given in chemistry to modern pharmaceutical problems, by Messrs. Frank Woods and F. L. Pyman, the staff of the pharmacological laboratories, in the lecture theatre, 17, Bloomsbury Square, on October 22nd and succeeding Thursdays, at 5.30 p.m. Admission to the first lecture without ticket; admission to subsequent lectures by ticket only. Tickets of admission to the course (fee 10s.) may be obtained on application to the secretary, 17, Bloomsbury Square, W.C.1.

The Services

No. 14 STATIONARY HOSPITAL DINNER

The twelfth annual dinner of medical officers of No. 14 Stationary Hospital, B.E.F., will be held on Friday, December 11th, at the Trocadero Restaurant, Piccadilly, at 7.15 for 7.45 p.m. Colonel C. R. Evans, D.S.O., will be in the chair. The address of the honorary secretaries is 39, Devonshire Place, W.1.

DEATHS IN THE SERVICES

Lieut.-Colonel Robert George Hetherington Tate, R.A.M.C. (ret.), died after a short illness at Louth, Lincolnshire, on July 17th, aged 52. He was educated at Trinity College, Dublin, where, after a distinguished student career, he graduated B.A., M.B., B.Ch., and B.A.O., in 1902, and obtained the M.D. degree and the D.P.H. in 1903. After acting as resident medical officer at Steevens's Hospital, he studied mental disorder at Londonderry, Omagh, and Banstead. He entered the R.A.M.C as lieutenant in January, 1906, and during his service in India he was officer in charge of hygiene and sanitation (Ambala area), and assistant to the C.M.O., Lahore Division, as officer in charge of the central laboratory. He went to France with the 6th Division in September, 1914, and in the first few months was twice blown up in the front line, after which he served as assistant to the C.M.O. of Étaples area, then of the Trouville area, and in 1918 was second in command of the 72nd General Hospital. In 1919 he was medical officer in charge of hygiene for the whole area of lines of communication. He was twice mentioned in dispatches, was appointed brevet-major in 1915, and acting lieutenant-colonel in 1917. From 1920 to 1923 he was assistant to the C.M.O. (Scottish Command) as officer in charge of hygiene. From September, 1923, to April, 1926, he was in charge of the military hospital in Newcastle, Jamaica. He retired from the R.A.M.C. as lieutenant-colonel on July 3rd, 1926. For the last five years he had been an assistant county medical officer for the Lindsey County Council, and resided at Louth.

Medical News

Professor D. P. D. Wilkie will deliver a lecture before the Harveian Society of London, entitled "The surgery of the spleen," on Thursday, November 19th, at 11, Chandos Street, W.1, at 8.30 p.m.

A meeting of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square, on Wednesday, October 21st, at 5.30 p.m. Papers will be read by Dr. R. S. Clay, Mr. T. H. Court, and Dr. G. M. Findlay.

The annual general meeting of the Society of Medical Officers of Health will be held at 1, Upper Montague Street, Russell Square, W.C.1, to-day (Friday) at 5 p.m. Dr. C. Killick Millard, M.O.H. Leicester, will deliver his presidential address on the legislation of voluntary euthanasia.

A meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, October 22nd, at 8.30 p.m. Dr. D. H. Geffen, medical officer of health, Enfield Urban District Council, will read a paper entitled "Causes of suicide." A discussion will follow.

The eighth dinner of the Royal Northern Hospital Past and Present Residents Dining Club has been arranged for Friday, October 30th, at Frascati's Restaurant, Oxford Street, W., at 8 for 8.30 p.m. The president, Mr. F. W. Harlow, will take the chair, and Mr. A. M. Zamora will be the guest of the evening.

The annual dinner of the Prince of Wales's Hospital Reunion Association will be held at the Trocadero Restaurant, Piccadilly Circus, on Thursday, November 26th, at 7.45 for 8 p.m., with Dr. J. Browning Alexander in the chair. Price of dinner (exclusive of wines) 12s. 6d.; no tickets will be issued. Members are asked to notify the secretary, Dr. Bertram H. Jones, 47, Queen Anne Street, W.1, of their intention to be present, stating number of guests.

The annual dinner of the staff and past and present students of the Royal Dental Hospital of London will be held on the evening of Saturday, November 21st, at the Trocadero, with Sir Norman G. Bennett in the chair. The members of the staff will be "at home" to all past and present students of the hospital on the same day from 9.30 a.m. to 5 p.m. Cases illustrating the scope of the work undertaken by the hospital, especially the treatment of children and the young, will be shown, and the various departments of the hospital and school will be open for inspection. Medical practitioners are cordially invited.

The Liverpool annual cathedral service in aid of the Royal Medical Benevolent Fund will be held at 3 p.m. on October 18th; preacher, the Right Rev. Bertram Pollock, Bishop of Norwich. The Lord Mayor and Lady Mayoress will attend. Members of the medical profession and their friends are cordially invited to this service. Tickets may be obtained from the honorary secretary, 28, Rodney Street, Liverpool.

In response to requests from those interested in archaeology and anthropology the exhibitions arranged in connexion with the Centenary Meeting of the British Association, at the Wellcome Historical Medical Museum, 54, Wigmore Street, W.1, will remain open until Saturday, October 31st. The museum will be open each day, excluding Sundays, from 10.30 a.m. to 5.30 p.m., admission free. The Egyptian exhibition includes the results of past seasons' excavations carried out by the Egypt Exploration Society at Tell-el-Amarna and Armant.

The October monthly missionary travel talk on the wireless will be given next Sunday, October 18th (St. Luke's Day). The speaker, Dr. Agnes Fraser, was for twenty-five years the comrade and helper of Dr. Donald Fraser, in the Scottish mission in Livingstonia, Nyasaland. Her talk on "Doctoring in Central Africa" will be given in the National B.B.C. programme from 4 to 4.15 p.m.

The Fellowship of Medicine and Post-Graduate Medical Association announces that the following lectures will be given at the Medical Society of London, 11, Chandos Street, Cavendish Square: October 21st, at 4 p.m., Mr. Kenneth Walker, "Prostatic enlargement" (no fee); October 19th, at 8.30 p.m., Dr. Maurice Davidson, "The clinical aspects of pulmonary fibrosis," and October 21st, at 8.30 p.m., "Intrathoracic new growths," in connexion with the series of M.R.C.P. evening lectures; fee for each lecture, 10s. 6d. A free post-graduate demonstration will be given at the Royal Waterloo Hospital on October 21st, at 3 p.m., by Dr. Kenneth Playfair, on "The value of the electrocardiograph in diagnosis"; and on October 23rd, at 2 p.m., at the Miller General Hospital, S.E., Mr. Arthur Gray will give a free demonstration of gynaecological operations. From October 19th to 31st a course in diseases of children will be given at the Hospital for Sick Children, occupying the mornings only, fee £5 5s. Courses during November will include medicine, surgery, and gynaecology, at the Royal Waterloo Hospital; neurology, at the West End Hospital for Nervous Diseases; ophthalmology, at the Royal Westminster Ophthalmic Hospital; and proctology, at the Gordon Hospital and St. Mark's Hospital. Copies of all syllabuses may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The series of post-graduate clinics arranged by the University of Sheffield was resumed on October 9th at the Royal Hospital, Sheffield, and will be continued till November 6th. From November 13th to December 11th they will be held at the Royal Infirmary. The clinics are open free to all medical practitioners.

A course of post-graduate demonstrations will be given at the Manchester Hospital for Consumption, Hardman Street, Deansgate, Manchester, on Wednesday afternoons at 4:30, commencing on November 4th, when Dr. H. R. Clarke will discuss the diagnosis and treatment of early pulmonary cases. All graduates and students of medicine are invited to attend. Tea will be served at 4.15 p.m.

The autumn session of the South West London Post-Graduate Association will open at St James Hospital, Ouseley Road, Balham, S.W., on Wednesday, October 28th, at 9 p.m., when Dr. R. G. Canti will give a film demonstration of tissue growth. The lecture demonstrations will be continued on succeeding Wednesdays until December 16th.

At a meeting of Southwark practitioners, held at the Evelina Hospital on October 6th it was decided to form a Southwark medical society. The meeting was addressed by Dr. A. F. Heald, organizing secretary of the London Panel Committee, and Dr. G. de Swietochowski, president of the Paddington Medical Society. Dr. E. Stungo was elected chairman, and Dr. J. McFadden treasurer and secretary.

The Socialist Medical Association, which was formed a year ago, has been granted affiliation to the Labour Party as a Socialist society, and is also affiliated to the International Socialist Medical Association. It includes in its programme "a socialized medical service, both preventive and curative, free and open to all." Further objects are the dissemination of the principles of socialism within the medical and allied services, and the stimulation of interest in health questions among members of the Labour, Socialist, trade union, and co-operative movements. The secretary is Dr. C. W. Brook, 72, Balham Park Road, S.W. 12.

Messrs. Ernst Leitz (Wetzlar) have recently completed their 300,000th microscope, which, in accordance with their usual custom of dedicating each 50,000th microscope to a famous scientist or institution, has in this instance been presented to Professor Dr. Ludwig Aschoff of the Pathological Department, Freiburg University, Germany. The following is a list of former dedications to eminent scientists and institutions on the completion of each 50,000th: German Sanatorium for Consumptives, Davos; Robert Koch; Paul Ehrlich; Professor Heidenhain; Institut fur Schiffs- und Tropenkrankheiten, Hamburg.

The October issue of the *Leprosy Review*, the quarterly publication of the British Empire Leprosy Relief Association, contains a valuable survey of the work of the League of Nations in connexion with the campaign against leprosy. Dr. Stanley Smith contributes a report on the progress in the Kigezi district of Uganda, and Dr. R. G. Cochrane comments similarly as regards Kenya, Zanzibar, and Tanganyika. Practical details of treatment are recorded by Dr. F. G. Rose, medical superintendent of the Mahaica Leprosy Hospital, British Guiana. Dr. Davidson of Emjanyana mentions that he has been using large doses of alepol, but has had to discontinue them owing to the severe general and ocular reactions. The report can be obtained from the offices of the Leprosy Relief Association, 29, Dorset Square, N.W.1, price 2s.

A further tribute to the memory of the late Professor W. E. Dixon is to be found in the issue for September 26th of the *Archivos de Medicina, Cirurgia y Especialidades* of Madrid, where he is described as one of the most eminent men of science in the United Kingdom.

Professor Pavlov has obtained 184,000 roubles from the Soviet Government to complete the building of his biological station at Koltouchi, near Leningrad.

On the occasion of the twenty-fifth anniversary of his professional activities, the students and friends of Professor Luigi Devoto, the founder and director of the Milan clinic for occupational diseases, have founded a prize of 10,000 lire, to be awarded every two years to the best work on industrial pathology. The work, which must be written in Italian, English, French, Spanish, or German, must be sent to R. Istituto Lombardo di Scienze e Lettere, Milan, by December 31st. Non-Italian competitors must send an abstract of their work in Italian or French.

In 1930 Vienna possessed 4,732 medical practitioners of whom 500 were women, and 1,823 dentists, or a proportion of one doctor to 380 inhabitants and one dentist to 1,000 inhabitants.

Letters, Notes, and Answers

All communications in regard to editorial matters should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proof.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 9861, 9862, 9863, and 9864 (internal exchange for all).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aetiology, Westcent, London*.
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westcent, London*.
MEDICAL SECRETARY, *Mediscera, Westcent, London*.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams, *Bacillus, Dublin*; telephone, 62350 Dublin); and of the Scottish Office, 7 Drumsheugh Gardens, Edinburgh (telegrams, *Associate, Edinburgh*; telephone, 24361 Edinburgh).

QUERIES AND ANSWERS

Survival after Prostatectomy

Mr. W. S. DICKIE, F.R.C.S. (Middlesbrough) writes: A man has just died aged 93. He had a pro-tatectomy done twenty-three years ago. I should be glad to know of any cases of longer survival.

A Special School Needed

"A. R." writes: Five years ago I attended a boy of about 6 years of age. His people said he was "rather funny-tempered." I found that he was slightly cretinous, and treated him with thyroid which acted very quickly. His father carried on the treatment, and I saw him once or twice when he told me how the child was going on. He was attending a preparatory school, and was very backward at his work. He has just gone as day scholar to a grammar school, and the other boys have found that he is slightly different from them, and are giving him rather a bad time. This is gradually throwing him back, and his father has asked me what he can do in the matter. I would like to know of any school that looks after this sort of youth. The boy is now 11. Reasonable fees can be paid.

Prophylaxis of Lumbago

Dr. E. PROTHEROE SMITH (Redditch) writes in answer to "S. L." (October 3rd, p. 637): This complaint is most commonly due to fibrositis around the sacro-iliac joints, associated with some arthritis, and giving rise to subluxation of those joints. I have for many years had attacks as described by "S. L.," and have found benefit from deep massage, radiant heat, Droitwich brine baths, and long courses of salicylates, but I have most faith in Salts (Birmingham) sacro-iliac belt—first recommended to me by Mr. Naughton Dunn—which holds the pelvis in a firm grip, is comfortable to wear, and enables me even during an attack to get about, drive my own car, and play golf. It is, of course, essential to eliminate nasal and oral sepsis—a case of mine was cured by extraction of one septic tooth. I have learnt to associate highly coloured and strong-smelling urine with the probable onset of an attack. For the immediate relief of pain I recommend dry cupping (by pump), novalgin, and gorun tablets.

Income Tax

Cash Basis—Sale of Practice

"A. C." has been advised that he will have to make up accounts on a bookings basis for the fifteen months to June 30th, 1931, when his sole practice was sold. He points out that he had brought that debts unpaid when a practice was sold were capital and not taxable.

*** Such debts are not taxable as income in the years in which they are received. It therefore A. C. was not required to deduct from the cash basis for the final periods he would include as income of those periods the

whole of the cash received thereon, but would not pay on the amount of the subsequent receipts As it is, his last accounts will exclude cash received in those periods in respect of earlier fees, but will include the value of fees for work done in those periods but paid for later Probably the ultimate difference will not be substantial

Cost of Maid

"D R" asks what is the general proportion of the cost of a maid's services—covering board and lodging in addition to keep—where she is employed partly on the professional portion of the premises

*** No general rule of any validity can be laid down, because so much must depend on other circumstances—for example, the size of the practitioner's family may considerably affect the ratio of private to professional employment Probably one half is a fairly common basis, but would never, or very seldom, be exceeded, and might be an excessive allowance in many cases

Earnings of Wife

"S M E" earns about £500 a year from panel and private practice, and his wife earns about £120 a year from professional (mostly locumtenent) work They use the same surgery etc but are not in partnership Can they claim to be assessed separately?

*** On the facts there appear to be two distinct practices and we consider that the earnings should strictly be assessed separately But provided that the facts are briefly stated to the inspector of taxes, and that "wife's earned income relief" is claimed the result is the same The relief in question for 1931 32 will be an addition of £45 to the married personal allowance of £150, making £195 in all

Cash Basis

"R T" is a partner in a firm which has for years been assessed on the basis of cash takings The inspector of taxes now insists that the "bookings" basis shall be applied after this year

*** In our experience a departure from the cash basis is not insisted on where there is reasonable ground for assuming that the true income is fairly steady—at any rate, is not showing a definite upward tendency Calculating liability from bookings and deducting a proper amount for bad debts and allowances is a troublesome task, because it implies some scrutiny of each debt outstanding at the end of the year to value it properly All this work is thrown away if the income of the practice is steady But if it is increasing then the cash income tends to lag behind the value of the bookings with the result that the cash basis is too lenient to the taxpayer If "R T" can show that the value of the year's work of the practice is *not increasing* we suggest that he again urges on the inspector the large amount of really valueless work he is asking to have done Unfortunately it is beyond dispute that the cash basis is not legally correct and that, strictly, outstanding bookings should be valued each year

Guide to Income Tax

"J A K" asks whether there is any book dealing with income tax from the general practitioner's standpoint

*** No We are not aware of any such publication, though some of the small guides contain classified information with regard to expenses deductible in the case of professional profits and similar assistance

LETTERS, NOTES, ETC.

Unilateral Convulsions in ? Diphtheria

Dr N M Mian writes I was called to attend one night a child suffering from fever duration one day On physical examination, the child had dyspnoea, and there were spasmodic convulsions present on the left arm and leg The child had fever (104° F) and looked very seriously ill Occasionally a peculiar shrill voice was also produced, and it appeared as if it was due to a spasm of the larynx Lungs were quite normal and pulse quick and full After excluding all the diseases characterized by spasmodic convulsion I suspected diphtheria, and so examined the throat. A definite cellulo plastic exudate was found covering the fauces and appeared to be extending downward into the pharynx and larynx Keeping the latter finding in view, I commenced treatment for diphtheria The very first dose of diphtheria antitoxin had so marvellous an effect on the health of the child that convulsions stopped next morning and dyspnoea became considerably less severe The dose when repeated, brought about normal temperature, calm and quiet breathing, and disappearance of the diphtheric membrane from the fauce The child recovered completely in about a week, and is, up till now, hale and hearty

St Mary's Hospital Dinner

Dr C M Wilson (dean of St Mary's Hospital Medical School) writes In your account of the annual dinner you refer to me as a defiant optimist, and proceed to do your best for me in that lonely role What I actually said was that the size of a medical school is ultimately determined by the size of the hospital attached to it and that if the board of management would provide a sufficient number of beds I would undertake that the expansion of the school did not lag behind I did not say that the Rugby club reached the final for the first time in its history Though my activities on behalf of that club have been exaggerated by the credulous, I am not ignorant of its history The club had been in the final half a dozen times before I entered the school.

Prescribing British

Dr Ian E McCracken (Gosforth) writes: There must be a considerable importation of Continental waters in bottle into this country, and while there appears to be no doubt about the value of these waters when drunk fresh from their source, yet doubts have been expressed as to their value after bottling and transportation For many years past a prominent physician at a leading Continental spa had been advising a patient of mine to drink a bottle of the spa water daily in the intervals between his periodical visits there In September of this year, however, this same physician wrote to me saying that he was convinced that the bottled spa water was valueless, and that as an alternative he was now prescribing for all his patients an equivalent quantity of plain boiled water to which had been added a squeeze of lemon and sufficient tea to produce a pale sherry-coloured beverage I give my experience in this connexion in the hope that others may feel that without detriment to their patients, they may help the reduction of imports

A Disclaimer

Dr Hubert Norman (Camberwell House, S E) writes May I correct a statement which has appeared in the press with reference to the Salvage case? I have been reported as stating that this man suffered from a peculiar form of insanity, which is liable to appear soon after the age of puberty, to reach its apex about the age of 23, and then to wane and pass away in the course of years Any such statement was published without my knowledge or authority and it is not descriptive of any form of insanity with which I am acquainted

Testimonial to Sir Ronald Ross

Further contributions to the Ross Award Fund since June 30th, including £1,000 from Mrs E B Holt (Brigg, Lincs), have brought the total amount to £15,409 1s 6d Donations should be sent to Lloyds Bank, Ltd, 110, High Street, Putney, S W.15

Medical Golf

There were seventy five entries for the Medical Golfing Society's meeting at Prince's, Sandwich, held by kind permission on October 10th and 11th The various competitions resulted as follows *Singles* v *Bogey*—Michael Smyth (6), 6 up, 1 H P Kolesar (scratch), 2 up, T A Torrance (plus 3), 1 up *Bogey Foursomes*—R W. Bristow and W H Lamplough won, after a tie with D S Gordon and L C Budge, at 4 up A C Rusack and H E Scoones, 1 up *Canny Ryall Cup*—H Gardiner Hill won with the very fine score of 71 plus 1 = 72 George Dawson 82 less 9 = 73, second L C H Budge (89 less 14 = 75) and H Chapple (85 less 10 = 75), third T. A Torrance, 73 plus 3 = 76

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 51, 52, 53, 54, 55, 58 and 59 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 56 and 57

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 231

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

333 Serous Meningitis and Infectious Mononucleosis

The former concept of "serous meningitis" was abandoned when the bacterial origin of inflammatory processes was demonstrated, but more recently some cases of "aseptic meningitis" have been recorded. A. Hecht Johansen (*Acta Med. Scand.*, July 27th, 1931, p. 269) records a case of infectious mononucleosis in which grave meningeal symptoms occurred at the onset of the illness. Johansen considers that the sequence of symptoms may assist in elucidating the etiology of this condition. A man, aged 28, was admitted to hospital suffering from "continued fever." Two weeks earlier he had had severe headache, drowsiness, and impairment of memory. He worked for one week, in spite of increasing headache and a morning temperature of 100.4° F., which rose at night to 102° or 103°. There were no rigors or sweating. He lay curled up, with closed eyes, and complained of agonizing headache. There was lassitude and some stupor with nuchal rigidity, but no dysphagia or sore throat, and no evidence of visceral disease, ear involvement, or ophthalmoplegia. Kernig's sign was present. The cerebrospinal fluid was clear but under pressure, and the cell count was increased; no bacteria were found, and the Wassermann reaction was negative for it as well as in the case of the blood. A differential blood count showed a definite lymphocytosis. An acute tonsillitis ensued, with a greyish exudate on tonsils, but no diphtheria bacilli were found. The tonsillar sloughs persisted until the third week after admission. The patient recovered completely after five weeks' illness. Johansen suggests that other cases regarded as "serous meningitis" associated with sore throat were actually cases of infectious mononucleosis, and that blood examinations should always be made.

334 Cardiac Influenza

H. L. G. Gérard (*Thèse de Paris*, 1931, No. 297), who records 17 cases in patients aged from 18 to 71, states that cardiac influenza consists almost entirely of functional disturbances, which may be nervous, myocardial, or neuromuscular (bradycardia). These functional disturbances do not as a rule outlast the period of toxi-infection, but in exceptional cases they may persist for a long time. In rare instances they may give rise to symptoms of severe cardiac insufficiency, which generally clears up under appropriate treatment without leaving any trace. The effect of influenza on pre-existing heart disease is extremely variable, but a possible aggravation must always be expected. The likelihood of recrudescence of infections such as syphilis or acute articular rheumatism must also be considered. The prognosis should always be guarded, even if the attack is slight.

335 Erythema Nodosum as a Tuberculosis Problem in School Children

A. Wallgren (*Nordisk Medicinsk Tidskrift*, August 1st, 1931, p. 493) regards as a bygone stage the teaching that erythema nodosum is a closed form of tuberculosis, for the investigations of recent years have shown that tubercle bacilli are often demonstrable in the swallowed sputum. Since the autumn of 1929, he has examined for tubercle bacilli the contents of the stomachs of 27 school children, between the ages of 7 and 14, suffering from erythema nodosum. In 12 instances he found tubercle bacilli, which had evidently come from a focus in the lungs. Only slight, or even negative, *x*-ray findings were recorded in 10 of these cases. In 10 other cases there were moderately well-defined *x*-ray changes in the lungs, and in the remaining 7 cases these changes were extensive. The more marked the *x*-ray changes in the lungs, the greater was the frequency with which tubercle bacilli were found in the contents of the stomach; among the 10 children in the first group, whose lungs showed few or no *x*-ray signs of disease, there was only one whose stomach contained tubercle bacilli. It is thus possible, by means of *x*-ray examinations and a search for tubercle bacilli in the contents of the stomach, to form a fairly definite opinion as to the infectiousness or the reverse in any given case of erythema nodosum in a school child. In order to ascertain the course of the disease when there is an open primary pulmonary focus associated with erythema nodosum, the author has repeated the examination of the contents of the stomach from time to time, of 6 children thus examined two months after the acute stage of the erythema nodosum, as many as 5 still harboured tubercle bacilli in the stomach. One child, in whom tubercle bacilli were repeatedly found, did not become negative in this respect till six months after the appearance of the erythema. It probably takes about half a year for a primary open tuberculous focus in the lung of a child to close, and during this interval the child should not be allowed to infect his healthy school fellows, but should be given sanatorium treatment.

336 Abdominal Pain and Skin Diseases

I. R. Trimble (*Journ. Amer. Med. Assoc.*, June 13th, 1931, p. 2010) calls attention (with notes of 15 cases—13 children, 2 adults) to a syndrome which is of importance in the differential diagnosis of acute abdominal conditions. It is characterized by the occurrence of the erythematous group of skin diseases (purpura, erythema, and urticaria) with abdominal and arthritic pains, angioneurotic oedema, and the presence of albumin, blood, and casts in the urine. The skin manifestations were the most constant, idiopathic purpura occurring in 14 instances, erythema in 6, angioneurotic oedema in 6, and urticaria in 5. Abdominal pain, sometimes severe, was present in all but two of the cases, and almost invariably preceded the appearance of the skin manifestations. Haemorrhages, small or large, in the bowel and mesentery may be revealed at an exploratory laparotomy, and are the obvious cause of the pain. Eight of the cases were accompanied by albumin, blood, and granular casts in the urine. The similarity to allergy in these cases is striking, but without bacteriological and immunological investigations the theory that these conditions are manifestations of an allergic phenomenon is not proved. All the patients recovered.

337 Asystole due to Right Ventricular Stenosis

E. S. Mazzei (*Rev. de Méd.*, July, 1931, p. 493) believes that the term asystole should only be employed in cases of total cardiac failure, and, since this is not always present, the terms right or left asystole are more correct. In 1906, Bernheim described a special type of right asystolic due not to dilatation, but to stenosis of the ventricle, which is caused by a marked deviation of the interventricular septum to the right. In this condition, named the syndrome of Bernheim, there are two periods of development. The first has an anatomical stage which is latent, insidious, and without clinical manifestations, and a clinical stage of more rapid evolution, characterized by the signs and symptoms of muscular incapacity of the ventricle. The second period also may be divided into two stages: that of obstruction attributable to stenosis, and the asystole proper. During the first of these there appear signs of retardation of the circulatory return in the venae cavae, such as dilatation of the veins of the neck and slight cyanosis of the face; these manifestations gradually extend to the extremities. In the second period, the terminal one, disturbances of the pulmonary circulation supervene. The characteristics of the syndrome then are: progressive right ventricular stenosis; failing of the ventricular myocardium; and displacement of the

ventricular septum, which in time increases the stenosis and adds more and more to the myocardial insufficiency. Post-mortem findings fully explain these signs and symptoms, and the pathological anatomy and pathogenesis of the condition are described. Short notes of two cases are also given.

338 Pseudo-Neoplastic Syphilitic Hepatitis

A. CADE and M. MILHAUD (*Journal de Méd. de Lyon*, August 20th, 1931, p. 487) state that in addition to the ordinary syphilitic perihepatitis, and the rarer purely gummatous type, there is a third form of syphilitic sclero-gummatous hepatitis which may produce hypertrophy and deformity, simulating a hepatic or extra-hepatic tumour, demanding surgical intervention. This so-called "surgical" type may assume a pseudo-neoplastic form, when cachexia follows changes in the shape, volume, and consistence of the organ. It may simulate primary cancer of the liver, or a secondary metastasis from another organ, and the differential diagnosis is often difficult. A specific history, and the clinical stigmata of chronic syphilis, are often absent. Splenomegaly is a very important indication, but this is not always present. Slow growth and minimal changes in the general condition suggest the possibility of syphilitic hepatitis, and the Wassermann test must always be employed. Exploratory laparotomy does not always determine the diagnosis, and it may be necessary to try anti-syphilitic treatment, preferably mercury and bismuth, which will usually give a favourable result unless they are employed too late. The authors have collected twenty-three cases. In a married woman, aged 46, there was a tumour of the left hepatic lobe, with chronic progressive nephritis; the spleen was not palpable, though the Wassermann and Hecht reactions were strongly positive. Full courses of neosalvarsan and of mercuric cyanide were given, and the tumour diminished in size. Nine months later the patient had a course of acetylarsan. Albuminuria and anasarca persisted, but the tumour had disappeared. Eighteen months later the urine was normal; the general health was excellent, but there was slight persistent oedema of feet. The Wassermann and Hecht reactions remained strongly positive.

Surgery

339 Mammary Enlargement following Prostatectomy

E. CONDOLEON (*Zentralbl. f. Chir.*, July 18th, 1931, p. 1821), who eleven years previously (ibid., No. 36) had published two cases of enlargement of the mammary glands following prostatectomy, has seen a similar case in a man, aged 62, who noticed bilateral mammary enlargement five months after suprapubic removal of adenoma of the prostate. The enlargement, which was somewhat tender, lasted a few months and then gradually subsided. [illegible]heimer (*Deut. med. Woch.*, 1927, No. 21) published [illegible]ear cases under the title of "Gynaecomasty following [illegible]omy." The occurrence of these five cases makes [illegible] that the association of prostatectomy and [illegible]nlargement is not a mere coincidence, and [illegible] explanations. According to the first, the [illegible]n internal secretion which inhibits the [illegible]he male breast; the second explanation [illegible]ation of the vasa differentia, usually [illegible]omy, disturbs the testicular function [illegible] mammary glands.

[illegible] child

[illegible] in Diabetes

[illegible] 104° F.) (*New Zealand Journ. of Surg.*, [illegible]liar shrill[illegible]ut that, since the discovery [illegible]d to surgical treatment in [illegible]ases charagreater than in non-diabetic [illegible]phtheria, anty in 73 cases of diabetes [illegible]c exudate w operative mortality in [illegible]be extendirent. The necessary [illegible]eeping the lost-operative acidosis [illegible]aling of tissues when operating on diabetic cases are as follows: a good state of general nutrition in the patient, abundant glycogen storage, freedom from ketosis, and a not unduly higher sugar content of the blood. The patient should not be dehydrated, since this predisposes to ketosis. Local anaesthesia is the most satisfactory; ethylene with gas and oxygen is reasonably safer, but chloroform and ether must be avoided. Insulin should be given three or four days before the operation, and a special daily diet containing at least 100 grams of high-grade, easily assimilated carbohydrate per day. About three hours before the operation, the patient should be given half to one ounce of oatmeal in the form of gruel, with two teaspoonfuls of glucose, preceded by a dose of insulin. After the operation, acidosis must be controlled by large amounts of insulin, and carbohydrate must be freely given, with 300 c.cm. of 10 per cent. glucose-saline solution by rectum immediately. Gangrene is the gravest surgical complication of diabetes; it occurs in about 3 per cent. of cases, and is most common in patients over the age of 60. The sequel known as "diabetic acute abdomen" is an occasional feature of marked ketosis or incipient coma, and may closely simulate an acute inflammatory abdominal condition of the abdomen. The differential diagnosis is difficult, and if any reasonable doubt exists, an exploratory laparotomy is justified.

Surge[illegible]was due to[illegible]d to surgical treatment in [illegible]ases charagreater than in non-diabetic [illegible]phtheria, anty in 73 cases of diabetes [illegible]c exudate w operative mortality in [illegible]be extendirent. 341 Intermittent Traction in Operations under Spinal Anaesthesia

[illegible] been a[illegible] (*Journ. Amer. Med. Assoc.*, June 13th, 1931, p. 2029) calls attention to the value of intermittent traction in spinal anaesthesia as a means of overcoming the uncontrollable vomiting reflex which is caused by the downward traction on the liver and stomach necessary to obtain adequate exposure. This annoying reflex can be almost abolished, it is stated, by a method of intermittent traction in which the patient assists in obtaining the required exposure by periodic straining on breathing out forcibly under compression. With forceps on the fundus of the gall-bladder the patient is instructed to strain or blow into a compression apparatus, thereby causing the liver to descend into the wound, where it is held by the forceps. After a few minutes' interval of natural breathing to allow the diaphragm to accommodate itself to the new position, a repetition of the straining causes the liver to descend further; after another interval at a third attempt the patient generally brings the liver sufficiently far down into the wound to allow of its rotation outward, thus affording complete exposure of the gall-bladder and common duct. The lesser curvature of the stomach may be similarly revealed by downward intermittent traction on the transverse colon and mesocolon. It is important to avoid too much traction, and to allow sufficiently long rest periods so that the diaphragm may accommodate itself to the new position of the liver or stomach.

342 Primary Synovial Tumours of Joints

D. M. FAULKNER (*Surg., Gynaecol. and Obstet.*, August, 1931, p. 189) reviews 27 cases of primary synovial membrane tumours of joints (a relatively rare condition) recorded in the literature, and reports 2 personal cases. These neoplasms may be divided into two groups, according as giant cells are present or absent. Their predilection for the knee is remarkable, 25 of the cases being of that joint. The etiology is conjectural, and some hypotheses are advanced as to their causative factors. A type of tumour, the myloplaxoma of the French, which was found in 10 cases, is described. These are not usually malignant. Excepting the synovioma described by Smith and the endotheliomata by Wagner, the tumours without giant cells are all defined as sarcoma of different types, and seem to be more malignant than those with the cells. Diagnosis is difficult, and is rarely made [illegible] operation. Though the prognosis is usually [illegible] these neoplasms, it must be guarded, for [illegible] known to cause death or to recur. [illegible] directed to preservation of life, saving [illegible] tion of joint function. As the possibi[illegible]

es at pages
d in the advertise-
at page 231.

is slight, conservative surgery is justified. In single, pedunculated tumours, early excision of the tumour and pedicle with resection of the synovial base of the pedicle should be made. In diffuse tumours, joint resection and arthrodesis are indicated. A course of radiotherapy should always follow operation. If, after conservative measures, the tumour recurs with invasion of other tissues, high amputation should be performed at once.

343 Gall-Bladder Function after Operations on the Stomach

Symptoms suggestive of gall-bladder disease sometimes follow gastric operations; since in many of these cases the food is passing directly from the stomach to the jejunum, it is possible that these symptoms are due to the absence of the normal reflex emptying the gall-bladder by the stimulus of duodenal contents. H. KALK and K. NISSEN (*Deut. med. Woch.*, July 17th, 1931, p. 1232) have therefore made a cholecystographic study of several cases after gastro-jejunostomy. In all cases the gall-bladder, sharply outlined by tetraiodo-phenolphthalein (injected intravenously), was seen to empty promptly when a meal consisting of egg yolk and cream entered the jejunum. In order to prove that this was purely a jejunal reflex, a similar meal mixed with barium was introduced directly into the jejunum by means of a duodenal tube. The gall-bladder emptied as before, though there was no reflux of the meal into the duodenum. The passage of the tube alone did not cause this effect, neither did the gall-bladder empty when egg yolk and cream were introduced into the stomach in a case of complete pyloric stenosis (before operation). It is concluded, therefore, that emptying of gall-bladder does not necessarily depend on a stimulus the duodenum.

Operative Treatment of Pott's Paraplegia

R. GIRDLESTONE (*Brit. Journ. of Surg.*, July, 1931, 21) advocates early decompression for Pott's paraplegia in adults. This may take the form of laminectomy, costo-transversectomy, or both, but stabilization by bone-grafting of the diseased part of the spine is an essential complement of decompression. Children suffering from spinal caries, if kept at rest long enough, with the spinal column relieved from strain and with metabolism stimulated by open-air conditions, rarely develop severe paraplegia, and can be cured without operation; but in the case of adults operative treatment is generally indicated. The cure of Pott's disease depends on good general health of the patient, and the restoration of spinal stability; by combining grafting with laminectomy the stability of the spine is increased. Paraplegia generally comes on in the first few months of Pott's disease, and the pressure almost always arises from an abscess, granulation tissue, or bone that is accumulating in front of the theca. If the paraplegia advances quickly or progressively during immobilization, decompression is relieved by costo-transversectomy or laminectomy, or both, and in addition a twin graft fixation should be performed to bridge the opening and counteract the local loss of laminae and spines. Early decompression removes the risk to the cord from prolonged pressure, and avoids the complications of paraplegia; the grafting, which helps to complete local immobilization of the spine, protects the spinal column from further erosion, and promotes healing of the lesion. In cases where *x* rays show a spherical, or fusiform but nearly spherical, prevertebral abscess, costo-transversectomy is performed first, and is followed a fortnight after by a graft, which is combined with laminectomy unless the paraplegia is improving. In cases where the paraplegia comes on late in the history of Pott's disease the prognosis is not good, although a case is reported which shows that operation even in a very late stage may be worth while. The technique of grafting is fully described in conjunction with laminectomy, and details are given of twelve cases where the combined operation with or without costo-transversectomy has been performed. In many cases complete recovery is reported; in others considerable improvement followed, but in three instances little or no improvement was seen. After operation the patient remains on his frame or plaster bed for three or four months.

Therapeutics

345 Emergency Treatment of the Alcoholic

I. D. WILLIAMS (*Journ. Nerv. and Ment. Dis.*, August, 1931, p. 161) believes that, in the treatment of alcoholism good methods of metabolic readjustment can be effected without the absolute withdrawal of alcohol, which frequently brings on attacks of delirium tremens. The therapy aims at securing better control of the sympathetic system, which, in this condition, has become entirely disconnected functionally from its cortical and organic control centres. Prompt catharsis is instituted by enemas, high irrigations, and saline cathartics for two or three days in order to reduce the water content of the body. The author claims that this is a true detoxicating process, though it is not directed against any specific toxin, which, indeed, he considers does not exist in alcoholism. In very acute cases in which Kernig's sign or other meningeal phenomena are present, lumbar puncture is indicated to reduce the ventricular pressure and to allow the removal of excess of fluid from the brain. The author argues that experience in poliomyelitis and other infectious conditions within the skull has proved the value of this procedure, and it may therefore be considered likely to be useful in the toxic encephalitic process of alcoholism. As regards medicinal treatment, a mixture of belladonna and hyoscyamus with the fluid extract of xanthoxylus, is recommended, in order to tone up the sympathetic nervous system. Great care in watching the effects of this medication is necessary in view of the possibility of individual idiosyncrasy. Alcoholic drinks may be administered at first with small amounts of water in order to satisfy the psychological demand. It is pointed out that the mere deprivation of alcohol does not remove the effects of previous indulgence, nor destroy the desire for it. By such definite and specific medical treatment as described the craving is reduced or abolished, and the patient is thus brought into a receptive state for the commencement of psychotherapy.

346 Toxoid Immunization against Diphtheria

H. H. RAY (*Amer. Journ. Med. Sci.*, August, 1931, p. 251) is satisfied that the toxoid immunization of children against diphtheria is safe and reliable. He has tried this method in the case of 358 children; of these, 333 received 2 c.cm. of toxoid, 98 per cent. being rendered Schick-negative, while twenty-five received 1 c.cm., and of these only 84 per cent. were immunized. In this series the toxoid was given in two injections of 1 c.cm. on each occasion, at an interval of ten days, and this routine was found satisfactory. The toxoid preparation contains approximately fifty times the amount of media and bacterial protein present in the toxin-antitoxin mixture. The fact that it is resistant to heat, retains its antigenic power, is non-toxic, and is free from horse serum makes it, in the author's opinion, a most desirable preparation. Both local and general reactions followed; their incidence was associated with the age of the patient, the varying possibilities of sensitization to the protein of the diphtheria bacillus of the media proteins, and the differing background of allergy in each case. Children under the age of 8 reacted much less frequently than those who were older. Ray concludes that from 90 to 98 per cent. negative Schick reactions may be expected after the administration of a total dose of 2 c.cm. of toxoid. If a dose of 1 c.cm. alone is given, the number of Schick-negative results usually falls below 90 per cent.

347 Indications for Acetylcholine

I. DAINOW (*Rev. Méd. de la Suisse Romande*, July 25th, 1931, p. 520) briefly reviews the action of acetylcholine, a derivative of choline, on man and animals; in the latter it acts markedly as a dilator of the arteries and arterioles. On this property are based its therapeutic indications. Acetylcholine is the treatment of choice in arteritis, intermittent claudication, Raynaud's disease, and post-operative trophic troubles of the extremities; it has also been used with beneficial results in numerous other conditions,

such as arterial embolisms, cerebral softening due to embolism or arterial spasm, varicose ulcers, scleroderma, and lead colic. The vaso-dilatation is particularly intense in the cutaneous region, feeble in the renal and splanchnic zones, and absent in the pulmonary area. The dose therefore varies from 10 grams to 1 gram daily according to the seat of the disease. The salt employed is the hydrochlorate, and this should be administered subcutaneously; intravenous injections are dangerous and should be avoided; intramuscular injections are less active, and oral administration and local applications are ineffective. Acetylcholine acts only as a vaso-dilator when the blood contains a relative excess of potassium; if an excess of calcium is present its action is reversed. Its use is therefore contraindicated after perifemoral sympathectomy, an operation which modifies the calcium-potassium ratio.

348 Treatment of Undulant Fever

G. S. Schilling, C. F. Magee, and F. M. Leitch (*Journ. Amer. Med. Assoc.*, June 6th, 1931, p. 1945) record a case of undulant fever in a farm labourer, aged 23, in whom the diagnosis was temporarily obscured by a positive agglutination of *B. typhosus* in a 1 in 40 dilution. *Brucella suis*, however, was isolated from the blood and faeces, and the agglutination test was positive in a dilution of 1 in 160. A highly concentrated, relatively soluble autogenous antigen was prepared, and after the intragluteal injection of 1 c.cm. there was a complete and permanent subsidence of the infection in forty-eight hours.

Neurology and Psychology

349 The Nerve Factor in Allergic Reactions

It has long been thought that psychic stimuli influence the occurrence of asthmatic attacks, but owing to the recent interest taken in the part played by allergy in this and similar diseases, the nervous factors have become neglected. F. Diehl and W. Heinichen (*Münch. med. Woch.*, June 12th, 1931, p. 1008) have sought scientific proof of the influence of the mental state by producing a skin reaction with a specific allergen injected intracutaneously, and injecting a second exactly similar dose while the patient was under hypnosis. The size of the second reaction in relation to the size of the first could be increased or reduced at will, by suggesting to the patient that it should cause more, or less, itching and burning than did the first injection. All the factors were controlled carefully, and it was found possible to increase or reduce the area of the reaction by as much as 60–80 per cent., although the normal variations according to the authors are not more than 15 per cent. They conclude that even where a definite allergen is found to be the cause of asthma or urticaria, psychic factors should not be lost sight of in treatment.

350 Treatment of Spinal Ependymal Gliomas

Owing to the dangers incurred in removing intramedullary tumours, treatment by *x* rays has been advocated, surgical measures being restricted to decompressive laminectomy. H. Cairns and G. Riddoch (*Brain*, June, 1931, p. 117) believe that certain intramedullary gliomas can be completely removed without serious permanent injury to the cord. Some spinal gliomas grow rapidly, are richly supplied with blood vessels, and are not sharply demarcated from the surrounding nervous tissue; such tumours are not favourable for surgical removal. Other ependymal gliomas, however, are quite circumscribed and of slow growth. Two such cases are fully described in which considerable recovery of spinal function followed complete excision of the tumours. In one instance the growth extended from the fourth cervical to the third thoracic segment; in the other, from the third to the fifth thoracic segment. Both tumours were quite circumscribed, and were bounded by a layer of compressed fibrillary neuroglia. The cord presented a fusiform swelling at the seat of the growth, and in one case there was slight dislocation of the posterior columns at the site of maximum swelling. Each tumour was connected to the cord by delicate strands, presumably of neuroglia. The cases differed greatly in symptomatology; the symptoms are discussed, and the immediate effects and results of treatment are reported in detail. Accuracy of diagnosis before operation and the need for long and patient after-treatment are emphasized. The authors conclude from these two cases that operative enucleation should have its place in the treatment of at least some intramedullary tumours.

351 Avertin Anaesthesia in Neurological Surgery

In intracranial surgery the inhalation of ether tends to induce swelling of the brain, post-operative vomiting, and pneumonia. W. E. Dandy (*Journ. Amer. Med. Assoc.*, May 30th, 1931, p. 1860) has therefore for a year been using almost exclusively avertin anaesthesia by the rectal method for all major operations on the brain and spinal cord. In more than 250 major cranial operations of every type there has been no mortality due to the anaesthetic, no case of post-operative pneumonia, and no immediate or remote deleterious effect. Moreover, owing to the absence of swelling of the brain it has been possible to reduce the size of cranial exposure in removing tumours, particularly in the case of growths affecting the hypophysis. Avertin was found particularly valuable in the cerebellar approach for partial section of the sensory route in trigeminal tic douloureux, while the complete removal of cerebello-pontine tumours was facilitated, and rendered more safe. Within five or ten minutes of the introduction of avertin into the rectum the patient passes into a sound, peaceful, and apparently natural sleep. Awakening is gradual, without nausea or vomiting usually, and the duration for several hours of loss of memory tides over the most uncomfortable part of the post-operative period. Owing to the length of the anaesthetic influence all necessary shaving of the head may be performed after the avertin has been administered, without encroaching upon the time required for the operation. Dandy remarks that previously reported unfavourable effects seem to have been due to overdosage; he regards the safe dose as being 90 to 95 mg. for each kilo of body weight. Rarely is a greater dose required, and the limit is 100 mg. per kilo; for an ill-nourished patient a dose as low as 50 or 60 mg. is sufficient for complete anaesthetization. Pulmonary lesions, chronic nephritis, and hypertension do not contraindicate its use. There is a marked drop in blood pressure, but this is unimportant, and need not be countered by adrenaline; no secondary depression ensues, and the blood pressure, having returned to the normal after the short depression period, remains steady.

Obstetrics and Gynaecology

352 Child-bearing and Pulmonary Tuberculosis

A. Leyland Robinson (*Journ. of Obstet. and Gynaecol. of the British Empire*, Summer, 1931, p. 338) remarks that Great Britain, despite the attention paid to the ordinary consumptive, makes no attempt to provide for treatment of the pregnant tuberculous woman. Pregnancy reduces the chance of admission to a sanatorium; on the other hand, active tuberculosis is rightly regarded as a bar against admission to the ordinary maternity hospital. He records the conclusions gained from 200 replies to a questionary sent to tuberculosis specialists (not gynaecological or obstetrical specialists), of whom forty were residing abroad in countries among which Germany and Austria are not included. The questions concerned the influence of child-bearing on pulmonary tuberculosis, and the broad general deduction seemed justified that the chances were 5 to 1 against pregnancy proving harmless to a tuberculous woman. Three-quarters of the reporters agreed that child-bearing, especially if repeated at short intervals, had a definite effect in causing development of tuberculosis previously "latent"; any apparently beneficial effect on tuberculosis during pregnancy was usually annulled after delivery. With few exceptions lactation was held to be

contraindicated, and the routine induction of abortion was rejected Induction of abortion, useless and possibly dangerous in late pregnancy, was recommended by a consensus of opinion in a small minority of cases of active disease Indications for it were (1) an early active lesion discovered in early pregnancy, (2) reactivation of a quiescent lesion in early pregnancy, and (3) the association of a mild tuberculosis with an obstetric complication reducing the patient's resistance It was clear that in general the tuberculosis expert had little practical experience of the result of therapeutic abortion, and Robinson advocates that in each case in which induction of abortion is contemplated there should be consultation between the practitioner tuberculosis officer, and obstetrician Therapeutic facilities are inadequate, there should be prolonged sanatorium treatment and discipline, skilled obstetrical supervision artificial pneumothorax when required avoidance of another conception for some time, with spacing of future pregnancies, abstention from suckling and special precautions with regard to infection of the child

353 Tumours of Mesentery Complicating Pregnancy

F Vozza (*Ann Ostet e Ginecol* May 31st 1931, p 501), who records a personal case, illustrates the rarity of the association of mesenteric tumours and pregnancy by the fact that he could find only nine other cases on record, all the patients recovered after operation According to Szenes, 52 per cent of all mesenteric tumours are benign, and 48 per cent malignant, metastases however, are rare In none of the cases was the diagnosis made before operation, the condition being mistaken for an ovarian tumour or a subserous uterine myoma Vozza's patient was a woman, aged 34, in the third month of pregnancy, she had suffered from attacks of abdominal pain for the previous two months, and presented a fluctuating and slightly tender tumour in the left lower quadrant of the abdomen A diagnosis of dermoid cyst of the ovary was made, and laparotomy was performed A tumour about the size of an orange was found between the layers of the mesentery, and on examination after removal proved to be a neurolipoma The patient made a good recovery and the pregnancy continued its normal course

354 Treatment of Gonococcal Vaginitis

In view of the fact that the vagina is less sensitive to heat than the vulva and perineum Dr C R Elliott has devised a means for the continual application of heat to the vagina at a temperature not tolerated by the external parts F C Holden and W S Gursef (*Amer Journ Obstet and Gynecol*, July 1931, p 87) describe this method, in which a bag is introduced into the vagina, and then distended to the required pressure with water at 115° to 120° the heat is increased by three quarters of a degree each minute until a temperature of 130° is reached This heat is maintained for the remainder of the hour In a patient having a normal mouth temperature the thermometer reading in the urethral meatus was 104°, in the bladder 104 1° in the anterior rectal wall 106°, and the posterior rectal wall 104° The heat from the bag is thus distributed in all directions Examination by speculum after treatment shows that the hyperaemia caused a marked increase in the cervical and vaginal secretions After two treatments the cervix is softened, and becomes shorter and broader, thereby causing a widening and shortening of the cervical glands The majority of cases showed a leucocytic increase This method of treatment has been found successful in cases of salpingitis, pelvic cellulitis and tubo ovarian or pelvic abscess The marked increase in the pelvic circulation causes a more rapid revolution in a shorter period of time than with any previous method adopted Since a temperature lethal to gonococci can easily be maintained for an indefinite period of time it proved an excellent treatment for gonorrhoea So far 5,233 treatments have been given in about 500 cases with only one severe burn, which was due to the negligence of a nurse The method is employed in association with rest in bed, bowel hygiene, and sedatives as needed With former methods of treatment the patient was discharged free from symptoms and pyrexia, but with *gonococci* still present, and a persisting pathological state of the tissues By the use of the hot water bag efforts are directed more towards a cure by causing absorption of the pathological exudates and removing the infecting organism, thereby preventing recurrence in the future

355 Transverse Cervical Caesarian Section

After performing 427 cervical Caesarian sections L E Phaneuf (*Surg Gynecol and Obstet* August, 1931, p 202) concludes that the transverse incision offers three distinct advantages it avoids encroaching on the uterine musculature and allows placing of the incision entirely in the lower segment the bladder separation need not be carried so far downwards and repeated operations are simpler to perform In this method the abdomen is opened by a median incision about 6 inches long The peritoneal cavity is entered between the bellies of the recti, and the lower uterine segment is walled off with gauze 1 c cm of gynergen is injected into the thigh muscles at this time The uterine peritoneum is incised transversely above the bladder reflection, and a transverse median incision is made as low as possible in the cervix The child is delivered by raising the head with the hand and pressing the fundus In breech presentations the infant is extracted by the feet and 1 c cm of pitocin is now injected into the thigh muscles If there has been no labour, or if the cervix is but slightly dilated, the placenta and membranes are expressed through the incision, if the cervix is fully dilated, the cord is replaced in the uterus and delivered by pressure through the vagina after closure of the cervical incision in two layers The peritoneal edge at the bladder reflection is sutured to the uterus above the incision The *gauze is now* removed the omentum brought down and the abdominal wall closed in two layers This operation can be readily performed under local infiltration and spinal anaesthesia

356 Ligature of the Ovarian Vein in Post-partum Pyaemia

F v Mikulicz Radecki (*Zentralbl f Gynak* June 13th, 1931 p 1897) agrees with Martens's recent advocacy of the Trendelenburg operation of venous ligature in puerperal pyaemia and with his preference for the extraperitoneal approach He records a successful case in which he is convinced transperitoneal operation would speedily have proved fatal The patient, who had three rigors from the seventh to the tenth day after labour, had signs of pulmonary infarction and staphylococci in blood culture she was in an almost moribund condition when, under spinal anaesthesia, the left common iliac and left ovarian veins were ligatured extraperitoneally Pyrexia had ceased a fortnight later The operation was confined to the left side because the left parametrium only was thickened, and the ovarian vein was found to be displaced to the outer side of the kidney A purulent metastasis in the left kidney pouch was drained at the same time

357 Vaginal Hysterectomy

F Montuoro (*Riv d Ostet e Ginecol Prat* July 1931 p 275) remarks that vaginal hysterectomy although now rarely performed in France (its original home) has recently gained an increasing vogue in other countries he cites the reports of four Austrian and German surgeons who record over 650 vaginal hysterectomies for fibroma with no mortality The abdominal route affords an easier operation, and one in which in certain cases conservative excisions of parts of the uterus only are facilitated but the operative risk is considerably greater By the vaginal route the shock is less and there is less danger of infection of the peritoneum It is indicated whenever possible, in cases of adiposity or cardio-renal disease the risk of post operative hernia or adhesions is diminished Admitting many contraindications to vaginal hysterectomy such as very large myomata, fixation of the uterus, and narrowness of the vagina, Montuoro concludes that the vaginal route is preferable in many cases in which the easier abdominal operation is undertaken n

Pathology

358 Estimation of Renal and Hepatic Function

M. Einhorn, W. H. Stewart, and H. E. Illick (*Med. Journ. and Record*, July 15th, 1931, p. 56) record their experience with uroselectan sodium, skiodan (a monoiodomethane sulphonate of sodium), and thorotrast (thoriumdioxysol). They found that 40 grams of uroselectan sodium in 100 c.cm. of water, injected intravenously, causes no untoward symptoms, and facilitates the radiographic study of the kidneys, ureters, and bladder, thus frequently obviating the introduction of opaque media into the bladder. The renal function can also be studied by determining the specific gravity of the urine one hour after the uroselectan administration, and estimating the precipitate after the addition of a few drops of nitric acid: a high specific gravity and large precipitate indicate good renal function, while but little increase in specific gravity and no precipitate show poor function. Uroselectan sodium is strongly antiseptic and its presence in urine prevents decomposition; though useful in urography it was found to be unsuitable for hepatography. Since its rectal administration causes bowel irritation, this method is contraindicated for urography, and skiodan, which contains 50 per cent. of iodine in firm combination, is preferable. Its aqueous solution is neutral, it is sterilizable by boiling, and it can be given either intravenously or rectally. Its antiseptic properties are similar to those of uroselectan, but it does not increase the urinary specific gravity, and there is no precipitate with nitric acid. Investigations in hepatography with thorotrast, administered intravenously, reveal its value, since in one patient the gall-bladder became visible within half an hour of the first injection, and remained so for two weeks after the third injection. In another patient the liver, spleen, and gall-bladder were visible fourteen days after the last injection, and carcinomatous metastases in the liver have been demonstrated by this means.

359 Erythrocyte Agglutinogens

F. Plattner and H. Hintner (*Wien. klin. Woch.*, July 3rd, 1931, p. 882) have been unable to confirm the observations of Hallauer and others that specific agglutinogens are only loosely attached to the stroma substance of the red cells, and may be completely or partially removed by washing repeatedly in normal saline solution. They find that the group specificity cannot be removed by washing, and cannot be regarded as having only a loose adsorptive connexion with the stroma; it forms an inseparable structure detail of the stroma substance. On the destruction of this stroma substance the specific isoagglutinogen probably passes into the extract, but from this it cannot be taken up into structural combination with foreign cells of another group, probably because [illegible] it in their structure. The isoagglu[illegible] corpuscle cannot be regarded as independent [illegible] there is no place for [illegible]a of the four human blood groups [illegible] inable properties can be differentiated by a superficial layer [illegible] ntigens. The stroma [illegible] soluble substances A and B; the [illegible]e not merely to be dis[illegible] independent agglutina[illegible]me [illegible] stinction lies deeper.

360 The Reticulo-Histiocytic Apparatus and Fat Metabolism

[illegible]Barelli (*Arch. dello Ist. Biochim. Ital.*, May, 1931, 215) finds that the endoperitoneal injection of oil, or of an III in an oily solution, does not cause in the rat the [illegible]ressive changes such as were first described in the [illegible]elium of the rabbit's ear by Fischer-Wasels and Ward. Contrary [illegible]he view held by some pathologists the stainable fat is always [illegible]nt in the secondary follicles of the rat's spleen. In [illegible]eripheral portions of the spleen of normal rats, [illegible]n some of those treated in various ways with injec[illegible] of oil and dyes, the author observed all the stages in the development of distinct [illegible]l stages from the reticulum cells with dislodging-shaped [illegible]ophil granules to young leucocytes with explain [illegible]12 [illegible] and sudanophil granules, which [illegible] the origin of the sudanophil granulocytes in the circulation. In several rats injected with vital stain or Sudan III in oil solution, giant-cell metaplasia was seen in the spleen. Study of the cell destruction in the secondary follicles showed that this followed a marked seasonal rhythm, being pronounced in the autumn, but absent or nearly so in spring and summer; this may explain the divergent views as to the function of the secondary follicles. Barelli has studied histological sections of fatty deposits in the liver from the seasonal standpoint, and finds that scanty deposits occur more frequently in the winter, while in the summer the deposits are abundant.

361 Humoral Changes in Insulin Hypoglycaemia

As a result of experiments on dogs to which large doses of insulin were administered, some being also anaesthetized, F. Rathery and J. Sigwald (*C. R. Soc. de Biologie*, July 16th, 1931, p. 1074) conclude that large doses affect the various plasma elements. Convulsions, observed in some of the animals, or signs of intolerance were independent of the anaesthesia, the insulin dosage, or the drop in the glycaemia. The plasma chlorine figure was constantly raised; the corpuscular and spinal fluid chlorine contents were variable. The urea was increased, and also the blood albumins, the latter not invariably. Changes in the spinal fluid sugar were variable and appeared more slowly than those of the glycaemia. The tension of the spinal fluid was lowered. Increase of the insulin dosage intensified the hypoglycaemia, and apparently exaggerated the symptoms, without influencing the increase of the plasma chlorine.

362 Blood Chemical Changes in Streptococcal Septicaemia

In order to ascertain the cause of death from streptococcal septicaemia in rabbits, R. W. Linton (*Journ. Exper. Med.*, August 1st, 1931, p. 223) performed experiments on 17, and describes the clinical changes which occurred in their blood. A broth culture of *Strep. haemolyticus* was employed. The animals were classifiable in two groups according to the clinical type; there was a fulminating form of disease, with an average survival of 61 hours following the injection of 0.5 c.cm. of the broth, and an acute form, in which the average survival period was 6 days and the dose of broth 0.4 c.cm. The blood sugar figure dropped at a constant rate, but did not reach the level of hypoglycaemia; glycogen was present in the liver at death. The CO_2 capacity was markedly lowered at first, and then returned to a somewhat higher level until the terminal stage, when the acidosis became very marked. Inorganic phosphorus was notably increased at the end of the disease, the rise being greater in the acute group. Calcium showed terminal decreases, which were less in the acute cases; non-protein nitrogen and creatinine were greatly increased in the terminal stages of both groups. The immediate cause of death apparently was severe renal changes due to the large amount of acid produced by the micro-organism.

363 Simple Test of Renal Function

A. Hellfors (*Deut. med. Woch.*, July 10th, 1931, p. 1193) describes a simplified technique for estimating the ability of the kidney to excrete alkalis. Before the first morning meal a specimen of urine is collected, the patient emptying the bladder as completely as possible; 15 grams of sodium bicarbonate in 400 c.cm. water is given by the mouth. Another specimen of urine is collected 1½ hours later, and a third half an hour after the second; a few drops of phenolphthalein solution are added to each, and should give a pink colour to the third, if not the second specimen, if the renal function is adequate. The test is recommended by reason of its simplicity, but gives no information as to the degree of renal failure. If the test is negative (no red colour in the third specimen) it should therefore be followed up by further tests; if positive, these are unnecessary. The alkaline urine in some cases of cystitis or pyelitis is a source of error, and there must have been no recent therapeutic administration of sodium bicarbonate.

Wherever calcium is prescribed . . .

Wherever calcium is prescribed for adult or child, order Ostelin Vitamin D as well, to ensure efficient utilisation.

OSTELIN VITAMIN D

("Ostelin")

In liquid form. Is compatible with other medicaments.

For incorporation in aqueous mixtures: in 8 c.c. phials, 2/6, also in bottles containing 4 and 8 ozs. for dispensing purposes.

Also OSTELIN TABLETS
OSTOMALT OSTELIN EMULSION

ADEXOLIN CAPSULES

Vitamins A and D highly concentrated

For general use in infective processes. To prevent and abort colds and other diseases of the respiratory tract. As a prophylactic during the later months of pregnancy.

In boxes of	per box

CLEANLINESS IS NEXT TO GODLINESS

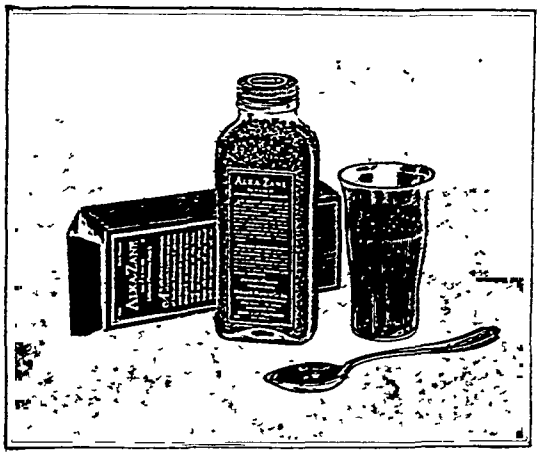
In cleanliness lies the key-note of success on the Preventive side of Dentistry. Many manifestations of Oral Disease and Dental Caries are due (either as a direct or contributary cause) to the effects of accumulations of extraneous matter and food debris around the teeth. If these are removed regularly, and the teeth themselves kept polished, such a state of constant cleanliness can be maintained in the mouth, that much dental trouble can be avoided.

These are the truths that are given such widespread publicity and force in all Gibbs National Advertising. Gibbs constantly remind the public that a little care and thoughtfulness in matters of dental hygiene is repaid a thousandfold in the preservation of the teeth, freedom from suffering and improvement in health.

Wherever the public is urged to use Gibbs Dentifrice twice-a-day, the phrase is complemented by the advice to visit the Dentist twice a year.

Always, in Gibbs propaganda, the Doctor and Dentist are represented as the highest authorities on all matters affecting the teeth; and as a result there is an increasing acceptance upon the part of the public of any advice or instruction given by Doctors and Dentists.

GIBBS DENTURE TABLET



Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The product has been approved by important members of the Medical Profession.

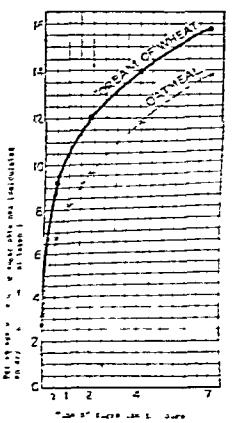
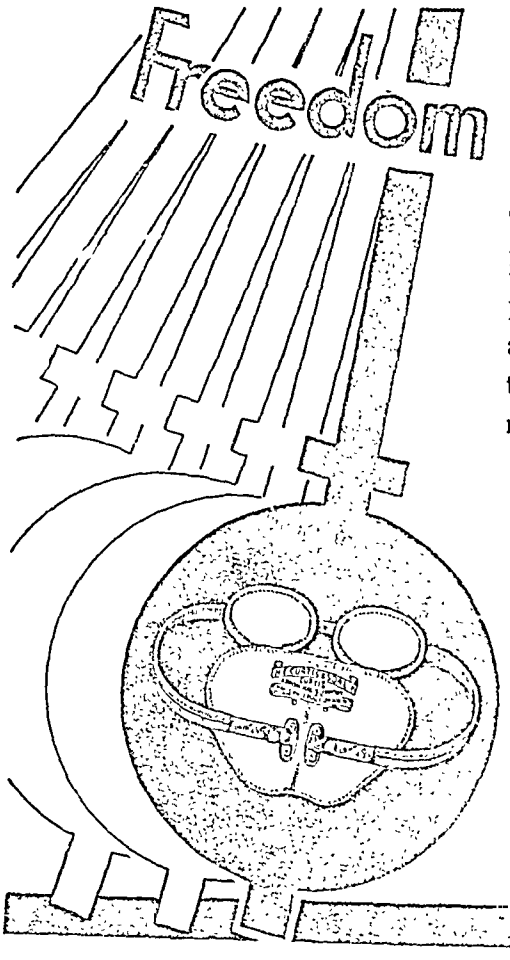
Research Institute investigates the relative value of wheat cereal and oats as first solid diet

Greater digestibility and 50% more energy intake proved for wheat

Tests by a leading biochemical institute have established the superiority of "Cream of Wheat" over oatmeal as a first starch food for infants. Some of the advantages are indicated in the accompanying graphs which summarize the results of careful experimental work on these cereals.

DIASTATIC DIGESTION





Not only did the digestion of "Cream of Wheat" continue at a scarcely diminished rate 4 hours after the digestion of oatmeal was practically at a standstill, but the amount of sugar yielded was 50% greater. "Cream of Wheat" thus affords 1½ times as much energy as oatmeal, and, by maintaining the blood sugar at an optimal level, helps to bring about the complete hydrolysis and metabolization of fats.

PANCREATIC DIGESTION

The growing tendency among practitioners to give starch as early as the third month makes these tests of paramount importance. Many leading paediatrists are putting "Cream of Wheat" on their diet sheets for infants.

It can be given both as a first solid diet—particularly for children prone to indigestion or fat intolerance—and as an adult food in the post-operative period. A sample and fuller details of the above tests will be gladly sent you on receipt of a professional card—Dept. W 10, Fassett & Johnson, Ltd., 55, Clerkenwell Road, London, E.C.1.

Freedom of Movement

The principle of the Curtis Abdominal Support Model No. 1 is that of anterior-posterior pressure, and is the only support that gives direct abdominal uplift without cramping or binding the hips, assuring the patient freedom of movement at all times.

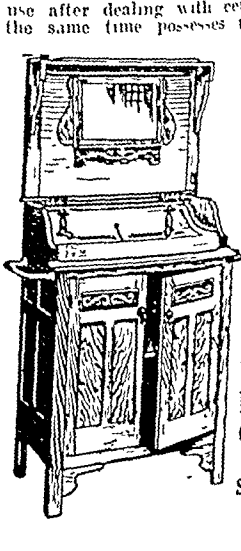
SENSIBLE EQUIPMENT for Consulting Room and Surgery.



The "HUE" Fire

The "Hue" fire is a constant money-saver in any apartment. Designed for scientific combustion it gives an amazing amount of heat, with a saving of not less than 33 1/3 per cent. in fuel. A "Hue" fire can be attached to your old type stove in a few minutes and will burn efficiently with cheap coal and cinders. Prices from 12/-, according to size and finish.

The "TOILEX" Cabinet

For a quick and constant supply of hot and cold washing water in the Surgery, the "Toilex" Enclosed Cabinet is the ideal installation. The "Toilex" satisfies perfectly the demand for a handy Lavatory Basin for use after dealing with certain cases, and at the same time possesses the tremendous advantage of being out of sight when not required, the top closing down and forming a very convenient table. Only very simple plumbing is required to fit it. Price £11, delivered free within 50 miles.

May we send illustrated literature showing the full range of "Hue" Fires and "Toilex" Cabinets.

English Trade Mark No. 276477 (1905)

Local Anæsthesia in Surgical Practice

CHRONIC ABSCESS OF RIGHT TIBIA

Typical Case.

Mrs. H. S. D., aged 29 years.

Diagnosis: Chronic osteomyelitis (bone abscess) of the right tibia.

Operation: Channelling excision of necrotic tissue and introduction of Beck skin flaps.

Anaesthesia: Circumferential infiltration block (90 c.c. of 1 per cent. Novocain-Adrenaline solution).

Technique of Anaesthesia: 90 c.c. of Novocain-Adrenaline solution was introduced circumferentially—the needle passing laterally and posteriorly to the tibia just below the knee-joint. A small discharging sinus was excised, the periosteum elevated, and a channel cut by means of the mallet and gouges, removing approximately one-third of the circumference of the tibia. A number of chisel points were broken because of the eburnation of the bone. The endosteum was found to be sensitive, but thorough curettage was made. Pedicle flaps were turned in on each side and good results followed.—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

THE TREATMENT OF **GOUT**

PISTANY

RADIO-ACTIVE MUD PACKS

PISTANY SPA REPRESENTATION,

38, Sackville Street, W.1. Tel. Regent 2638.

Pistany (Czechoslovakia) offers the most effective treatment for the cure of gout.

Special provision is made for the diet of gouty patients in the hotels.

In mild cases a few weeks suffice to relieve the condition but the need for prolonged intermittent treatment often makes a course with Pistany Mud Cubes or Compresses at home, under the patient's own doctor's supervision indispensable for a complete cure.

The method of application is safe and inexpensive for Pistany's sulphur Mud is inert and sterile of mineral content and keeps indefinitely.

Send for interesting Medical and Tourist literature.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent. DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the most scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is a trout stream in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

Phone 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms prospectus, etc., apply MEDICAL SUPERINTENDENT.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, Violet Light, Diathermy and Foam Baths. Apply, Dr. D. E. M. D[illegible]

A Private Mental Hospital for the Treatment and Care of Mental and Nervous Disorders in both sexes.

Now removed to:

CHISWICK HOUSE,
PINNER,
MIDDLESEX.

Telephone: PINNER 234.

A modern country house, 12 miles from Marble Arch, in beautiful and secluded grounds.

Fees from 10 guineas per week.

Voluntary Patients received for treatment.

Special provision for "Temporary" patients under the new Mental Treatment Act.

DOUGLAS MACAULAY, M.D., D.P.M.

TREATMENT of EARLY MENTAL CONDITIONS

Medical Men having cases presenting any of those numerous states of ill health and disability now more generally recognised as often primarily due to minor psychoses and neuroses, and in need of investigation with view to decide on the treatment best likely to promote recovery and to prevent further mental deterioration, are invited to apply for particulars below, where for some years past a number of such cases, in both sexes, have been successfully dealt with.

The number in residence at any one time being strictly limited, close individual attention can be given, whilst the patient is provided with a comfortable home life in pleasant surroundings, with suitable occupation for leisure hours.

Certified cases and those definitely certifiable are not accepted.

RESIDENT PHYSICIAN, Elmsleigh, Bassett, Southampton.

The MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.

Telephone: RODNEY 4641–2.

W. W. HORTON, M.D. Nat. Tel. 153

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week, beginning on October 19th, 1931.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings; all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30·5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 66

Valentine's Meat-Juice

In the Gastric Form of Influenza and its Debility, in Typhoid and Acute Pneumonia, in the Exhaustion of Phthisis and Pulmonary Diseases, Valentine's Meat-Juice Sustains and Strengthens.

When Other Food Fails

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

J. & A. CHURCHILL

"RECENT ADVANCES"

"A series unparalleled among medical publications."—THE PRACTITIONER.

"Methods of treatment change so quickly that such publications as the 'Recent Advances' Series are invaluable to the general practitioner, too busy, as he usually is, for post-graduate study."—BRITISH MEDICAL JOURNAL.

"The 'Recent Advances' Series published by Messrs. J. & A. Churchill meets a want in medical literature by providing a concise, yet sufficiently detailed, summary of developments in the theory as well as in the practice of the various specialities into which medicine is gradually resolving itself."—EDINBURGH MEDICAL JOURNAL.

SUCCESSFULLY PRESCRIBED FOR MANY YEARS

SULPHAQUA

IN THE TREATMENT OF

Skin Diseases, Rheumatism, Gout, Neurasthenic : : Conditions in Arthritic Subjects, Etc. : :

And as a valuable addition to the Inunction TREATMENT OF SYPHILIS with Mercury.

EMPLOYED IN BATH AND TOILET BASIN.

Possesses powerful Antiseptic, Antiparasitic, and Antalgic properties RELIEVES PAIN AND INTENSE ITCHING Soothing and Sedative in effect WITHOUT OBJECTIONABLE ODOUR, and does not blacken the bath enamel

SULPHAQUA SOAP Recommended for the Skin and Hair. Especially useful in the treatment of Acne and Seborrhoea of the Scalp Largely used in dermatological practice

In Boxes of ½-doz. and 1-doz. BATH CHARGES, 2-doz. TOILET CHARGES, and ¼-doz. SOAP TABLETS.

Samples and Literature on Request *Advertised only to the Profession*

THE S. P. CHARGES CO., Manufacturing Chemists, St. Helens, Lancs.

"SULPHAQUA" is stocked by the leading Wholesale Houses in Canada, Australia, New Zealand, South Africa, India, USA

STANIFORM

Regd BRAND *Trade Mark.*

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds etc

DUSTING POWDER
For application where a greasy substance is contraindicated

LINIMENT
Is markably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men

"After using 'Staniform' Ointment in cases of Impetigo and other skin conditions of the skin I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform' Ointment"

'Festering wound on left heel—when first seen was about the size of a shilling with a good deal of pus Foot much swollen—dressed with Staniform Ointment—healed splendidly in four days'

Similar testimony has been received from a large number of medical men when Staniform has been used for the treatment of Burns, Wounds and Skin Ailments

STANIFORM is used in Leading Hospitals

STANIFORM over a wide field of clinical experience has exhibited positive curative properties Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine Staniform is indicated generally in local inflammations, inducing an immediate effect with rapid healing"

WHICH EXISTS TO PROTECT YOUR INTERESTS AND SAVE YOUR MONEY.

The Nation can save £80,000,000 every year

Every year the Smoke Evil costs this country more than £80,000,000 in wholesale waste, unnecessary labour, transport delays and damage to health and property.

The Smoke Evil is caused by the burning of raw coal in our factories and homes.

The use of gas and gas coke will help to save this £80,000,000, and enable the nation to enjoy the blessings of sunshine and clean air.

In the last 15 years the number of gas appliances in use in London has more than doubled; the sootfall has been more than halved.

For Smoke Abatement data and for information on the uses of gas and gas coke in home and industry write to the address below.

Riley
AS MODERN AS THE ROAD

"Plus-ultra" Two-Seater Coupé

will get you there just every time and additionally provides ample and convenient accommodation for the impedimenta you must carry with you. For instance, in the dash there are two Yale-locked cubby holes, and built into the rear of the body a large and commodious locker, also yale-locked, accessible from either interior or exterior. It is a handsome car, possessing all the Riley individuality, both in appearance and performance—has a large dickey seat, drop head and Triplex opening screen and windows. You can see it at

the "Blue Spot" at Olympia

(Stand 106)

or we will gladly arrange a demonstration on receipt of your request.

RILEY (COVENTRY) LIMITED, COVENTRY, & 42, Nth. Audley St., LONDON, W.1

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me"*; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE"

"ARDENTE" is entirely different and unequalled and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged or old, and so sensitive as to have the desired effect even in middle ear and nerve cases bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

Day or night

An IMPROVED and MODIFIED
Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates of Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions

Extension of whole lower limbs.
Movements about hip-joint.
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35in X 15in. X 11in.

5 QUESTIONS ANSWERED BY INDEPENDENT AUTHORITIES

	Question	*Answer*
1	Is aluminium a normal constituent of vegetable and animal life?	The majority of investigators are agreed that aluminium is definitely a normal constituent, and some are of the opinion that it is even an essential constituent of animal life
2	Is aluminium, whether introduced into the system either by the mouth as in food for example, or by subcutaneous injection, absorbed and returned, or does the body reject and eliminate all excess?	The answer is in nearly all cases to the effect that there is no appreciable absorption
3	Is aluminium harmful in the sense of producing toxic disturbances directly or indirectly of gastro intestinal origin, or alternatively in the sense of depriving food-stuffs of their nutritional or hygienic value?	The majority of investigators are definitely of the opinion that small doses of aluminium compounds (some 50 mg.) are completely innocuous, and may be taken continuously without ill effect. The German State Board of Health specifically mentions 1·600 mg. as being completely harmless to human beings. It is generally accepted that aluminium has no effect on the nutritive quality of food-stuffs
4	Is aluminium dissolved from utensils in the normal process of cooking to any important extent?	Opinion is agreed that traces of aluminium are undoubtedly dissolved especially with certain food-stuffs of an acid or alkaline nature, but the quantity is extremely small
5	Do aluminium compounds when taken in large or small quantities favour the development of cancer or other malignant diseases?	Scientific evidence is unanimous in showing that they do not

Telephones: Langham 1-11, 1-12.

Secretary: A. Rupert d'Avigdor

ON most of the occasions when you find it especially necessary to recommend woollen underwear it is a serious matter and worth a little serious thought. To carry the suggestion a step further and say not only wool but Wolsey is a piece of discretion, for Wolsey Underwear has long been known as the finest and healthiest woollen underwear made. Scientific investigations* have proved that garments made of wool do more than any other to prevent the depo ition of moisture on the skin; retain warmth better than any other material, and allow the most equable body temperature possible. Such is Wolsey.

* *By the British Research Association for the Woollen and Worsted Industries, detailed reports of which will be sent free on application to Wolsey Ltd., Leicester.*

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

Alasil" completely overcomes this objection By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Ana'gesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore

LIVOGEN

Livogen is a palatable liquid preparation containing the therapeutic principles (including Vitamins B_1 and B_2) of fresh liver, together with measured amounts of haemoglobin and additional Vitamin B. It is pre-eminently suitable, therefore, for administration in secondary anaemias, blood impoverishment and in all general conditions of debility in which a blood regenerating tonic is indicated. Livogen is particularly valuable as a vitalising tonic after illness.

Livogen is available from the principal pharmacists, in bottles of 4 fluid ounces, also in bulk packages for dispensing purposes.

For the treatment of pernicious anaemia, Liver Extract B.D.H. is still the product of choice.

ACCEPTED AMERICAN MEDICAL ASSN Council on Pharmacy and Chemistry

IN URINARY INFECTIONS

Pyridium has all the qualifications of an ideal urinary antiseptic—it is chemically stable; it is non-toxic and non-irritating; it exerts an antiseptic action in high dilution in either acid or alkaline urine; it is early and gradually eliminated in the urine in sufficient concentration to exert a continuous local antiseptic action; it is administerable by mouth.

Pyridium exerts more than a local effect—it penetrates the tissues and reaches the submucous areas not ordinarily accessible to therapeutic agents.

TRADE **PYRIDIUM** MARK

Effective in coccal, B. Coli and mixed infections, Pyridium is indicated in cystitis, pyelitis, urethritis, prostatitis, epididymitis, vaginitis, cervicitis, salpingitis and gonorrhoea.

Pyridium is the registered trade mark of the Pyridium Corporation of New York, to designate its preparation of phenyl-azo-alpha-alpha-diamino-pyridine hydrochloride.

Literature and REDUCED prices of Pyridium products on request.

MENLEY & JAMES, LTD., 64, HATTON GARDEN, LONDON.

Effective Ferrotherapy

IDOZAN IS A COLLOIDAL IRON SOLUTION, NEUTRAL, AND CONTAINING 5 PER CENT. OF PURE IRON (Fe).

One teaspoonful of IDOZAN contains 25 ctgrms. of pure iron (Fe).
One dessertspoonful of IDOZAN contains 50 ctgrms. of pure iron (Fe).
One tablespoonful of IDOZAN contains 75 ctgrms. of pure iron (Fe).

Thus, by means of relatively small doses of IDOZAN it is possible—without any inconvenience to the patient—to give much larger doses of iron than could be accomplished with many of the older preparations. In cases of severe anaemia, for instance, one may very well give the patient one tablespoonful of IDOZAN three times daily. This dosage means a daily intake of 2.25 grams of pure iron.

Packings—8-oz. & 40-oz. bottles.

DOES NOT CONSTIPATE
DOES NOT DISCOLOUR THE TEETH
DOES NOT PRODUCE STOMACH DISCOMFORTS

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

Nutritional anaemia in infancy

IT has recently been shown that breast milk does not contain an adequate amount of iron and that from the early days of infancy it is necessary to supply iron to the organism, if healthy development of the child is to be attained.

The organic iron in Virol from Glycerine Extract of Red Bone Marrow and from yolk of eggs is absorbed with ease.

The vitamin-containing Fats are very finely emulsified; they are therefore, easily digested by the most sensitive alimentary tract at all ages, including earliest infancy.

All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure.

VIROL

Mineral salts: vitamins: balance: digestibility

Virol is sold in Jars at 1/3, 2/- & 3/9, ½-gall. 15/- - - - - Virol, Ltd., Ealing, London, W.5.

WHAT SUGAR for BABY?

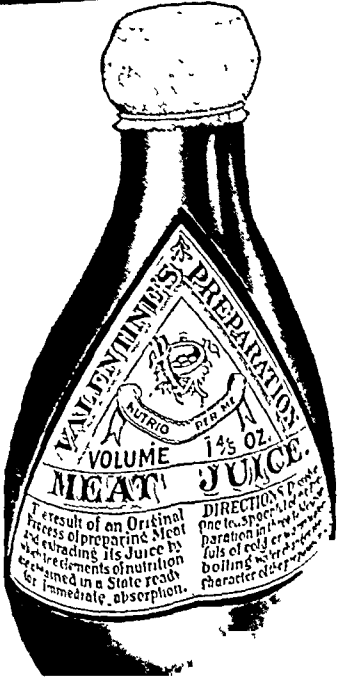
Calorific measurements indicate that all sugars have equal value, but physiological tests prove that some sugars are much more easily utilised than others. THE RELATIVE GAIN IN WEIGHT when maltose is used is nearly 40% greater than when cane sugar is employed. Maltose is more quickly absorbed and produces greater gain than any other carbohydrate.

Mellin's Food

is the standard malto-dextrin preparation for modifying milk alike for infants and invalids.

Produces greatest gain.

Entails least expenditure of energy.



Samples and booklet containing full details of composition and calorific value of mixtures suggested for different ages and conditions, post free, from:

MONSOL

BRAND

LIQUID GERMICIDE

1. It is far less toxic than many preparations of its class.
2. It has a selective action on Streptococcus Pyogenes, in particular on the strain Haemolyticus.
3. It is remarkably penetrating, but bland in action and has no harmful effects on the skin or mucous membranes.

Monsol is obviously, therefore, the perfect germicide for all Maternity work . . . whether the case is attended by complications or not. Obstetricians who have used it are enthusiastic in its praise.

Sample for clinical trial from the manufacturers. Other Monsol Products include Pessaries, Capsules, Throat Pastilles, Dental Cream, and Medicated Soap.

MOND STAFFORDSHIRE REFINING CO. LTD., ABBEY HOUSE, WESTMINSTER, S.W.1.

SURFACE THERAPY

THERMOGENE brand of Medicated Wadding is the ideal counter-irritant for routine use. It acts by stimulating the cutaneous nerves, sending reflex impulses to deeper areas where they bring about vascular changes.

Pain is eased, and congestion is relieved, by the flow of fresh blood, with consequent de-toxication and cleansing of the affected part.

Unlike poultices, pastes, ointments, and oily liniments, THERMOGENE brand of Medicated Wadding does not clog the pores of the skin or soil the linen.

THERMOGENE brand of Medicated Wadding is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

"Eucortone"

(Cortical Extract of Suprarenal)

In the treatment of

Addison's Disease

Efficacy established by biological tests and clinical use

(*Journal of Physiology*, June 6, 1931: *Proc. Physiol. Soc.* May 2, pp. 4, 5, and 9)

"Eucortone" is prepared by the method of Swingle and Pfiffner, and is highly successful in the treatment of Addison's Disease. Particularly striking is the rapid restoration of appetite, weight, strength, and feeling of well-being. Biological tests and clinical use show that "Eucortone" contains the long-sought cortical hormone in an active state and is free from adrenalin activity. The extract contains no irritant or toxic substance, and is sterile.

1 c.cm. is equivalent to 30 grams of cortex. In rubber capped bottles of 25 c.cm.

Further particulars on application.

'Euvalerol' Elixirs

for the treatment of

Nervous Disorders

The "Euvalerol" Elixirs are prepared from fresh valerian root by a special process which, while ensuring the retention of the active principles contained in the volatile oil of valerian, eliminates the objectionable odour that ordinary valerian products have.

"Euvalerol" Elixir A

contains the odourless preparation of valerian in Aromatic Elixir. Each fluid ounce is equivalent to approximately one fluid drachm of Tinct. Valer. Ammon., B.P.

"Euvalerol" Elixir B

is "Euvalerol" Elixir A with the addition of phenyl barbitone gr. ½ to each fluid drachm, and with a lighter tint, for ease of identification.

"Euvalerol" Elixir C

is "Euvalerol" Elixir A with ammonium bromide gr. 30, strontium bromide gr. 15, and a small amount of sal volatile, in each fluid ounce. It has a darker tint than the two other "Euvalerol" Elixirs.

For Prescribing: 4 oz. and 8 oz. bottles. For Dispensing: 40 oz. and 80 oz. bottles.

The Original & Standard
Emulsion of Petroleum

Angier's Emulsion is made with petroleum specially purified for internal use. It is the original pettroleum emulsion—the result of many years of careful research and experiment.

Bronchitis, Sub-Acute and Chronic. There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases. Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing, "comforting" effects.

Pneumonia and Pleurisy. The administration of Angier's Emulsion during and after Pneumonia and Pleurisy is strongly recommended by the best authorities for relieving the cough, pulmonary distress, and difficult expectoration. After the attack, when the patient's nutrition and vitality are at the lowest ebb, Angier's Emulsion is specially indicated because of its reinforcing influence upon the normal processes of digestion, assimilation and nutrition.

In Gastro-Intestinal Disorders of a catarrhal, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. The minutely divided globules of petroleum reach the intestines unchanged, and mingle freely with intestinal contents. Fermentation is inhibited, and inflammation of the intestinal mucosa rapidly reduced, and elimination of toxic matter greatly facilitated.

ANGIER'S EMULSION

ANGLO-SAXON SCULPTURED CROSSES.—These crosses are some of the most beautiful monuments left by the pioneers of the earliest English culture. They are abundant in England and far surpass in quality those in every other part of Europe. The inscriptions upon them are in Runes mingled with some Latin characters; their condition is such that decipherment and interpretation are still a subject of study .... Certain of the Runes on the cross here reproduced consist of groups of verse in the Northumbrian dialect; these are religious and Christian in content, but their exact translation is still a vexed question. The Runic inscriptions indicate, of course, the Teutonic authorship of the crosses. The ornamentation is composed of classical, Oriental, Keltic and Teutonic elements mingled in the Northumbrian manner. The drawing of the figures is remarkably good, although it is among the best to be carried out in this country.

Prevent Winter Infections

By starting prophylactic measures at once and continuing them till the spring, susceptible patients may be effectively protected against the common winter infections — influenza and pneumonia, bronchitis and recurrent colds.

Adexolin capsules, each of which contains the vitamin A content of three to four drachms of high-grade medicinal cod-liver oil and the amount of vitamin D normally found associated in cod-liver oil with that amount of vitamin A, offer a simple, economical, and scientifically well-established means of conferring such protection. The anti-infective action of these vitamins has been demonstrated both by controlled laboratory investigations and a growing clinical experience, and 2 capsules daily would appear to give a considerable increase in the body resistance.

Vitamin A, the first line of defence, exercises its anti-infective action by preserving the integrity of epithelial tissues, vitamin D reinforces this action by maintaining the calcium and phosphorus content of the blood at an optimal level and enhancing its bactericidal power.

In cases of acute infection Adexolin brings down the temperature and pulse rate, promotes resistance, and hastens the resolution of the infective process. To achieve this end Adexolin must be given in large doses.

ADMINISTRATION In the treatment of very acute infective processes the maximum dose which is tolerated without causing nausea or sickness may be administered. This is usually one or more capsules every hour. This dose may be varied, however, at the discretion of the doctor. As a general tonic one may be given three times daily, and this alone seems to raise considerably the resistance to infections.

The Harveian Oration

ON

HARVEY: THE MAN, HIS METHOD, AND HIS MESSAGE FOR US TO-DAY

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, ON OCTOBER 19TH, 1931

BY

ROBERT HUTCHISON, M.D., F.R.C.P.
PHYSICIAN TO THE LONDON HOSPITAL

the short time at my disposal I propose to direct ention to some aspects of Harvey's character and per-ality, to the intellectual atmosphere in which his great covery came to birth, and to the message which he has our own day.

The main biographical facts of Harvey's life are well own to everyone here, and Sir Wilmot Herringham, in his cinating Oration two years ago, gave us some interest-details about the Harvey family. When all is said and e, however, we really do not know very much about n, for, as Sir Wilmot said, Harvey had a singular acity for slipping through life unnoticed. We do not n know whether he attained that happiness at home ich, according to Dr. Johnson, is the ultimate result all ambition; for he was childless, and Mrs. Harvey is y a shadowy figure in the background of his life. It is ity that he had no Boswell. If he had, we should not y have known many more details of his walk and versation, but we should have had more of his preg-nt sayings, such as those recorded by Aubrey: "that n is but a great mischievous baboon," and "that the ropeans know not how to order or govern their women, that the Turks are the only people who use them ely," and of those *obiter dicta* scattered throughout his tings—"Many things are discovered by accident"; den were first let to cultivate philosophy by wondering what they saw," and so forth. As it is, we might say Harvey as the present Poet Laureate has said of kespeare:

hat we know little of his human relationships is one of the sed facts about him. That we conjecture much is the alty a nation pays for failing to know the genius when he ears."

CHARACTER OF HARVEY

Fortunately, however, the main outlines of Harvey's racter are writ large in his works, indeed few scientific ters are more self-revealing.

And first of the characteristics so revealed I would his *love of truth*. There is no word commoner in his tings than "truth," and we may be sure that none s oftener on his lips. "My trust," he boldly declares, s in my love of Truth"; or again, "I avow myself the tsan of Truth alone." Like all great discoverers he ms to have had a flair for truth, and that "fanaticism veracity" of which Huxley spoke, and doubtless he s ready, as Huxley also was, to follow the truth into atever abyss it might lead him. It was one of the atest compliments that he ever paid to the Fellows of s College that he assumed that in this matter they were -minded with himself. "I even ventured to hope," says, "that I should have the comfort of finding all t you had granted me in your sheer love of truth, ceded by others who were philosophers like yourselves." Next perhaps to his love of truth was his *reverence Nature*, which seems to mean in him the same thing reverence for the Creator. He appears to have had at Einstein calls a truly religious feeling in face of ture. "Nature, perfect and divine, is ever in the same ngs harmonious with herself." "Nature ever labours h foresight and intelligence." "That which is in conformity with Nature is right." "There is nothing either more ancient or of higher authority than Nature." "In Nature, just as there is nothing lacking, so there is nothing superfluous." These, and many similar quotations which might be made from his writings, reveal his attitude. In his reverence for Nature he reminds us indeed of some of the great poets. He would have perfectly understood Nature as the "Old Nurse" and would have subscribed heartily to the affirmation that "she never yet betrayed the heart that loved her."

Equal to his love of truth and his reverence for Nature was his *charity*, using the word in the scriptural sense. Of no man can it more truly be said that he envied not, vaunted not himself, was not puffed up. "Whilst I think the industry of everyone deserving of commendation," he says, "I do not remember that I have anywhere bepraised my own." He did not "behave himself unseemly," for, as Willis pointed out, all his public actions known to us were marked not only by propriety but by grace, and it was as true of him as it was of his royal master on the scaffold, that he "nothing common did nor mean." He sought not his own and was not easily provoked. Even when his papers and scientific records were destroyed by the mob—which he says was the worst crucifixion he ever had to endure—his only comment is: "Let gentle minds forgive me, if, recalling the irreparable injuries I have suffered, I here give vent to a sigh." Finally, he thought no evil ("to return evil speaking with evil speaking I hold to be unworthy of a philosopher," he said), but, as we have seen, rejoiced in the Truth.

Imagination, if by that we mean the creative faculty of the mind whereby it moves outside experience, was not so conspicuous in Harvey as it has been in many famous discoverers. The *De Motu* shows little of it. His argument in that great book proceeds forward, almost in pedestrian fashion, from position to position, till at last he is driven, as it were against himself, to see the truth; and his other book, the *De Generatione*, shows fancy rather than imagination. He was not one of those who saw a truth before he proved it. His mind did not take a sudden imaginative leap from the particular to the general, as Darwin's did, nor did he use all his faculties together to reach a result intuitively by a process hardly to be observed or analysed. He was more like Hunter in his love of facts, but he saw quickly the significance of facts within his experience, and perhaps that also is imagination.

Few great men, said Dr. Arnold, have lacked *humour*, and there are indications that Harvey was not wanting in this priceless gift, though his humour was probably of a sub-acid and rather sardonic sort, and his laughter would not be the "sudden glory" of Hobbes. There is humour in his description of his discovery of an egg in the dead body of Mrs. Harvey's parrot, which had all its life been supposed to be a male, and his account of his visit to the reputed witch at Newmarket is also full of it in a quiet way. His contemporaries evidently had some trust in his humorous sense, as is shown in Selden's amusing description of the cure of a person of Quality "with two devils in the head" in which he secured Harvey's co-operation. He was able also to see humour even in little things.

"How pleasantly are we moved to laughter," he writes in the *De Generatione*, "when we see the poor hen following to the water the suppositious brood of ducklings she has hatched, wandering restlessly round the pool attempting to wade after them to her own imminent peril, and by her noises and various artifices striving to entice them back to the shore."

His sense of humour must have been of value to him, not only in furnishing him with hints of truth, but in enabling him to face with equanimity the prejudices of

his Galenic contemporaries, just as Galileo, no doubt, found it helpful in facing the Inquisition and in enabling him to murmur, as he rose from his knees after his recantation, "*Eppur se muove.*" For humour, as Mr. Graham Wallas reminds us, is a powerful instrument for clearing away what Carlyle described as "the dead pedantries, inveracities, and accumulated dung-mountains" of scientific as well as of social, political, and religious thought; nor need we have any doubt that Harvey was always able to recognize in himself what W. K. Clifford called the still small voice that whispers "Fiddlesticks."

Reflecting upon the sense of humour in Harvey, it is permissible to regret that it is a quality not more abundant in scientific workers and writers. It would save us from much pedantry and dullness, from much solemn trifling calling itself research, and it would make scientific literature immeasurably more readable.

Love of truth, reverence, and charity, with some tincture of imagination and humour—these were the chief features of Harvey's personality; but to complete the picture we must add moral courage—which Michael Foster said is an essential part of the scientific character—patience, and reflectiveness. It must have required much moral courage to attack the Galenic stronghold, and it is no wonder that Zachary Wood apostrophized him as "Truly a bold man, indeed, O disturber of the Quiet of Physicians! O Seditious Citizen of the Physical Commonwealth!" His patience was shown not only in the carrying out of his investigations, but in his reluctance to make them public. He always bided his time. He was like Darwin, who waited twenty-nine years for the results of a single experiment, and all of whose work on evolution was published after he was 50. In his slowness to publish he resembled other great men of his time and of the next century—Galileo, Newton, Bacon, Cavendish, and Gauss. How different from us to-day, with our "preliminary notes" and disputes as to precedence in discovery! Lastly, he was a reflective philosopher. Like Hunter, his delight was to think. We are told that he would withdraw himself to the leads of his house in town, or to caves in his garden in the country, in order to indulge in contemplation. Surely in this, also, he has a lesson for our unreflective time.

Personality in Science

I have dwelt at some length upon the main features of Harvey's character because, in so doing, I believe that I am strictly fulfilling the injunction laid upon me to-day to commemorate the benefactors of this College. For, whilst we are grateful to our material benefactors, we owe an equal debt of gratitude to those who have conferred upon us the benefaction of their example. Of these Harvey himself is chief, but the College has reason to be thankful that it has never wanted amongst its Fellows men who were like-minded with him, but who—mute, inglorious Harveys as they were—lacked the touch of genius, or perhaps only the opportunity, which would have made them famous as he is.

In these days, when it is the fashion to denigrate great men, it is pleasant to remember that no one has yet seriously attempted to belittle Harvey. William Hunter, it is true, tried to depreciate his share in the discovery of the circulation, but he made no reflections on Harvey's character, whilst the curious statement made in a letter from Izaac Walton to Aubrey that Mr. Warner had told Lord Winchester that he (Warner) "had first found out the circulation of the blood and discovered it to Dr. Harvey, who said that 'twas he himself that found it," may probably be dismissed as apocryphal. No, on this our festival let us boldly praise famous men, and on St. Luke's Day let us be grateful, not only for the great discoverer, but for the man who exhibited in his character so many of the virtues of the Beloved Physician.

Apart from these domestic reasons, peculiar to this College, there are wider considerations which make the study of the character and personality of Harvey, as of those of all great discoverers, of interest. What part, we may ask, does personality play in the highest scientific work?

In art, of course, the personality of the artist is everything, and the same is true of literature—the style is the man himself. But in the case of science the influence of personality is not so obvious. There is a tendency, indeed, to regard scientific men as machines who discover facts and laws by a purely intellectual process with which character has nothing to do. This, surely, is too narrow a view. Truth is as many-sided as human nature, and requires the whole man to discover it. The great scientist must not only love truth as Harvey did, but he must have a feeling also for the beautiful and for the good. For truth is perceived by the emotions as well as by the intellect, and the poet and the discoverer are to some extent one. Moral qualities also are required, such as honesty and a sense of justice. Of course, all scientific men do not possess these qualities. There is no type of mind which can fairly be described as scientific, for there is no intellectual specialization *ab initio*, and scientific men are as full of prejudices and weaknesses as others; Harvey himself, let us be thankful, was neither saint nor sage. In proportion, however, as the emotional and moral elements in his personality are developed and cultivated will be the likelihood of the investigator attaining to the truth. In the words of Pascal, "It is only the great souls who attain to the utmost limits of science," or, as Harvey himself put it, "Nor does God give that which is most excellent and chiefly to be desired—wisdom—to the wicked." The real investigator must have faith, hope, and charity: faith in the object of his quest and in his power to reach it; hope to enable him to overcome all obstacles in his way; and charity, that is love of the truth, and, in medical science especially, love also of mankind.

And if personality is important in the attainment of truth it is surely equally important as Truth's advocate. The comparative absence of opposition to Harvey's discovery was no doubt partly due to the disarming modesty with which, like Lister, he gave it to the world, just as on the contrary Pasteur's aggressive cocksureness aroused the resistance of his contemporaries. But if personality is of importance in science in general, it is even more important in medicine, which is both a science and an art, and in the application of medical science in practice the personality of the doctor is as dominant as that of any other artist. Nor is its importance likely to lessen in future, for as investigation ceases to be individual, and becomes more and more collective, so will it be essential to have leaders who, by their personality, can attract and control the subordinate workers.

If, then, personality is so important both in our science and in our art, it is surely matter for congratulation that our College, in selecting Members for the honour of the Fellowship, has always considered not intellectual attainment alone, but the character and quality of the whole man.

The Intellectual Climate of the Seventeenth Century and of To-day

But Harvey's gifts of character and intellect, notable though they were, would not alone have enabled him to make his great discovery, and, like all innovators, he owed much to his predecessors. It is not usually difficult to trace the pedigree of great ideas—Einstein's theory is, perhaps, an exception to-day—for discoveries rarely spring to life full-grown like Minerva from the head

Jove. What Harvey owed to his predecessors in antiquity, and especially to Aristotle, has been shown by our learned registrar, Dr. Raymond Crawfurd. He derived much from the Italian anatomists, and no doubt also from his contemporary Galileo, the real founder of modern science, while his probable debt to Bacon and to Gilbert has been pointed out by Sir William Hale-White. All this is now familiar ground, and I do not propose to go over it again, but as "we are more children of the age we live in than of our own fathers," Harvey must be regarded as having been fortunate in the climate of opinion, to use Glanvil's phrase, in which his discovery came to birth. It has not always been so, of course. It is possible for a discovery to be born into an uncongenial mental climate, as Servetus and Semmelweis, to mention only two examples, found to their cost. But in Harvey's case the time was ripe for the man. Standing between the sixteenth and the eighteenth centuries, the seventeenth partook both of the credulity of the one and the scepticism of the other. It owed much to the Renaissance and more, perhaps, to the Reformation. It was a time of great awakening and renewal—the *Instauratio Magna* of Bacon. Scepticism and doubt, the active doubt which Goethe praised, were replacing credulity and dogmatism. Men were learning to trust reason rather than authority, to assert the liberty of individual judgement, to set the natural above the supernatural, and to look to the future rather than to the past. The imagination of the age had been kindled by the Copernican Theory and by the new orientation of man to the universe which it brought about, as well as by the geographical discoveries of the preceding epoch. The century owed much, also, to its great poets. It has been well said by Buckle that it was no accident that Shakespeare preceded Newton, for the poets not only stimulated imagination, but led men back to nature. Finally, as Dr. R. O. Moon has shown, it was an age greatly indebted to its philosophers, to Bacon, Descartes, and Spinoza especially, who created a spirit of scepticism and inquiry. Stimulated by their ideas, more men than ever before were turning away from the barren controversies of religion and devoting themselves to scientific pursuits, and these men animated and encouraged one another.

The practical results of the new outlook were also becoming apparent. Modern anatomy and physiology had already come to birth with the publication of Vesalius's great work only a generation before Harvey. Chemistry was emerging from alchemy, just as astronomy had already done from astrology, and in the early years of the century the science of physics also sprang into being. Nor was the revolt from authority seen only in science; it was being carried by Bacon into philosophy, by Hobbes and Glanvil into metaphysics, by Cromwell into politics, and by Harrington and Algernon Sydney into the theory of government. It was a time, in short, when anything seemed possible.

It is interesting to contrast the spirit of the age of Harvey which I have depicted with that of to-day. Like him we live in a period of great unrest—political, social, and economic—but in our own age there has been a destruction of values, a throwing down of standards, and removal of moral and intellectual landmarks of which the seventeenth century knew nothing. As a recent writer has said:

> "Behind both the good and the evil manifestations of that age lay a philosophic absolutism and a certitude of conviction now lost. Even those men who had shaken off some prejudices and particular beliefs retained the conviction of the eternal and absolute validity of truth and duty—a conviction of the dignity of man and of the worth of his work still illuminated human thought."

The effect of the moral and intellectual chaos of our age has been disastrous to the arts, and to some extent to literature, but it has not yet affected science. It may be, as Sir Frederick Andrewes suggested in his Oration more than ten years ago, that Western civilization is now in a state of decline, but that science, as has always happened before, is affected last. We may even have to look in future to science for our poetry—and indeed there is more of the spirit of true poetry in the writings of the modern cosmogonists than in all the anthologies of neo-Georgian verse. But if the march of science shows no signs of slackening, at least we have lost the scientific optimism which inspired Bacon's *New Atlantis*, and which was shown even more conspicuously by the scientific writers of the mid-nineteenth century. We are to some extent disillusioned with the results that science has yielded us. We are not so sure that the "Universe is friendly" after all, and that human life may not be merely "a discreditable episode in the history of one of the meaner planets," nor have we yet adjusted ourselves to the discoveries of modern astronomy any more than many men of Harvey's time had adjusted their beliefs to the great discovery of Copernicus. But this attitude is not likely to diminish the zest with which medical science in particular is pursued to-day. Never, on the contrary, has there been a time when conditions were more favourable for it, or when it and the practical benefits it brings were more sought after, for in our day the doctor has replaced the priest. This very popularity, however, has its own dangers. What we have to fear is the influence of the mass-mind, of the increasing importance attached to quantity rather than to quality in life, the undervaluation of knowledge for its own sake, and the exploitation of discovery for commercial ends. We may suffer, also, from the deflection of science by the pull of the politician, the philanthropist, and the press.

On the other hand, in all that concerns the apparatus of knowledge we have immense advantages compared with the seventeenth century. In Harvey's day there were no laboratories; scientific societies were only being founded, and scientific journals did not exist. The diffusion of new knowledge was slow and difficult, and investigators communicated their ideas and discoveries mostly by correspondence. How different it is to-day, when we have more laboratories than trained men to work in them, when societies have multiplied to a point when it is difficult to get audiences to attend them, and when our scientific periodicals are counted by the thousand. But these things also have their drawbacks. In Harvey's time Latin was the *lingua franca* known to workers in science in all countries. To-day anyone who aspires to be a scientist must know two or three modern languages besides his own—to say nothing of American. The accumulation of knowledge, too, is overwhelming. Look round this room in which we are met. It is a noble library indeed, but is it not also a mausoleum? And how many facts which men are at present hunting for, and theories which are even now being put forward as new, lie already buried in these shelves? No, we do not suffer to-day from starvation of the intellect: our danger rather is that science may become suffocated in its own secretions; and that a remedy should be found for this congestion and plethora of the scientific body is one of the most pressing needs of our generation. Again, in the time of Harvey there was no specialism, and it was still possible for a man to say that he took all knowledge as his province. Now specialism has been carried to the point of a vice, and the right hand of science does not know what the left is doing. We may agree with Sir Arthur Keith that specialism is inevitable as medical science evolves, but none the less we may be permitted to regret it. For specialism, however favourable to the

accumulation of facts, is bad for the philosophy of knowledge The worker in one province is too absorbed to notice what those in other provinces are about, indeed, the terminology of the different specialties is now become so esoteric that other workers cannot understand it if they would There is, in consequence of this, too little speculation and too little use of the imagination, and, compared with the wealth of knowledge and the brilliance of observation which it exhibits, most scientific literature is barren in ideas It would be good for us all, perhaps, if there was a close time in laboratory work and the publishing of papers for, say, five years, in order to give us leisure to digest the huge accumulation of knowledge which we already possess and to think out new lines of advance

Certainly the men of the seventeenth century, considering their inferior opportunities, did in this respect much better than we They showed more imagination, they were less afraid of speculation, and, alike in the solidity of its substance and in the perfection of its form, their work compares favourably with ours It is true, of course, that our times are unpropitious to reflection, and we may well say, with the Victorian poet, though with better reason even than he

> 'But we brought forth and reared in hours
> Of change alarm surprise—
> What shelter to grow ripe is ours?
> What leisure to grow wise?'

But let us take courage again from the example of Harvey He also lived in troublous times, yet he was able to abstract himself from the turmoil around him, and in thought and meditation to possess his soul in quiet

Conservatism in Medicine

It might have been supposed that Harvey's great discovery, born into such a congenial intellectual climate, would have been accepted everywhere and at once, yet we know that in fact, some time elapsed before the truth was generally recognized There was nothing new, however, in this Truth has always had to fight its way "How difficult it is, said Pasteur "to obtain the triumph of truth Jenner, Simpson, Lister, and Darwin all had the same experience It may be, as Mr Wilfred Trotter would have us believe, that the truly scientific mind is altogether unafraid of the new, but, if so, the truly scientific mind must be rare For history shows that prominent men of science have often themselves been the chief opponents of new truth Simpson opposed Lister, Liebig opposed Pasteur, Owen opposed Darwin In the seventeenth century Bacon rejected the Copernican theory, and poured scorn on the work of Gilbert on the magnet Even Harvey, as we know, refused to recognize the demonstration of the lymphatics We may flatter ourselves that new truth would have a better chance to-day, but the long neglect of Mendel's work, and that of Henri Fabre, should be a warning to us

This conservatism of science is at first sight surprising, and it is of interest to inquire into the causes of it Archibald Pitcairne ascribed the opposition to Harvey's discovery simply to ignorance and jealousy, whilst a recent American writer Mr Stern, using the language of modern psychology, has attributed it to such mental factors as fear reactions in the presence of the unknown and difficulty of reconditioning behaviour pattern along with cultural influences such as the power of tradition and authority, and ignorance of the experimental method On the other hand, a modern English critic of science, Dr Murray, thinks that the excessive conservatism of medical men is largely due to our habit of "laying down the law," as he puts it, to our patients I prefer, however, to all these explanations, the simple one of Bagehot that "the greatest paradox to human nature is the pain of a new idea"

But, none the less, a great deal may be said in defence of the conservative attitude It may be a good thing for truth to fight for its existence, for it is only by prevailing that it is proved to be truth As Dr Johnson said, "It is open to any man to state what he believes to be the truth, and it is open to any other man to knock him down, martyrdom is the test" We may even call Harvey himself as a witness in the defence of conservatism "The authority of the ancients" he says, "is not to be readily thrown off," and again "Everything is not to be received at once with an unthinking credulity" We speak with approval of the virtue of the open mind, but there is also something to be said for the closed mind, for it is often forgotten that an ever-open mind is like an open drain, it is apt to be the receptacle of a great deal of rubbish There are times when we should have the courage to say of the new, "This is not true, or, if it is, it has no right to be" Especially in medicine is a reasonable conservatism to be commended We dare not hazard the lives of the patients entrusted to us on the chance of a new theory being sound, or a new drug both useful and safe We must first prove all things—and that takes time—and if there were more conservatism and less credulity in our profession we should be saved from the ephemeral fashions in pathological doctrine and in methods of treatment which do so much to bring contempt upon our art

I would therefore venture to claim it as not the least of the services of this College to Medicine, that we have always, alike in matters of policy and of practice, adopted an attitude of wise conservatism

Observation versus Experiment

It is one of the duties of the Harveian Orator to remind his hearers of Harvey's injunction that they should "study and seek out the secrets of Nature by way of experiment" However necessary in Harvey's day, this exhortation has become superfluous in our own The experimental method has gone from one triumph to another, and now dominates the whole field of science, and its services to medical science in particular were eloquently brought before us by our late President, Sir John Rose Bradford, when he delivered his Oration four years ago But to those whose work lies in the clinical field, Harvey's advice must always have seemed a counsel of perfection For how is one to apply the experimental method at the bedside? The imperious demands of practice leave little leisure for the planning and carrying out of experiments whilst the claims of humanity restrict the application of the method in the case of the individual patient. It need excite no surprise, therefore, that some of the most earnest investigators in our science have suggested that a special class of clinicians—spoken of as research physicians—should be called into existence who should devote their whole time and energies to searching out the secrets of disease by the experimental method both in the laboratory and in the ward This is not the occasion on which to discuss this proposal in detail It is easy to see practical difficulties and objections, but on the day of all others it is a proposal which, in principle, should secure our sympathy We may be certain that Harvey would have approved it Indeed, it is difficult to imagine a position which would have been more to his own taste and more adapted to his abilities than that of "research physician"

But whilst we welcome any plan which offers a chance of increasing the application of experiment in practice of medicine, it does not follow that we must turn our back

upon the old traditional clinical method of observation. The respective merits and scope of the two methods, experimental and observational, have lately been discussed by some of the acutest minds in our profession, and I do not intend to reopen the controversy, though it may be well to point out that the two methods are not mutually exclusive. Harvey himself was a great observer. This is apparent in all his work as an investigator, and had his projected volume of medical observations ever seen the light of day we may be sure that he would have appeared as a great clinical observer also. Devoted though he was to the experimental method, he frequently urges the duty of observation. "Diligent observation is requisite in every science," he says, "and the senses are frequently to be appealed to." And again, "We are of opinion that for the acquisition of truth we cannot rely on the theories of others, except there be added thereto a diligent course of observation." It has been said by someone that in experiments we question Nature; in observation we only listen to her. True, but we shall question Nature in vain unless we listen to her replies. In other words, there is no real opposition between experiment and observation, for experiment is only observation carried out under artificially limited conditions and on a selected group of phenomena.

Nor can we agree with those who would have us believe that no further advances by purely observational methods are to be looked for. It may be that in countries of the temperate zone the clinical field has been so thoroughly gleaned that there would seem to be little chance of anything which mere observation can detect remaining unknown. We must remember, however, the saying of Bacon that, "noble inventions may be lying at our very feet and yet mankind may step over without seeing them." Even in recent years new diseases and "clinical syndromes" have been discovered and their natural history described by the observational method. It will suffice to mention epidemic encephalitis and acrodynia (pink disease) as examples. The fact also that such an obvious and striking phenomenon as the Babinski reflex has only been recognized since many of us here present were students should suffice to give us pause. No, the possibilities of clinical observation are not yet exhausted. In the domain of tropical medicine, for instance, great though the advances in recent years have been, there is still much field-work to be done. Clinical observation, going hand-in-hand with experiment, is throwing fresh light on the problems of epidemiology, whilst the enormous progress which this century has seen in psychological medicine has, from the nature of the material, been almost entirely along observational lines, and there is also scope for the study, by observation, of purely subjective symptoms, such as pain. Of the three members of the clinical triad—diagnosis, prognosis, treatment—the first is certainly coming to depend more and more upon the help of laboratory methods, but pure observation can still do much in the other two. The comparative neglect of prognosis especially is surprising, and any young Fellow of the College who is prepared to devote a lifetime to the collection of his observations, might, in his later years, produce a treatise on the subject which would make our whole profession his debtor. It is the same with therapeutics. Pharmacology has done much for us, and many recent advances we owe to laboratory experiment, but in the last resort any method of treatment must stand or fall by its actual results in practice, and it is here that we are in need of more extensive, accurate, and controlled observations. For if the observational method is to yield results of any value, either in the sphere of treatment or any other, the observations must be accurate and controlled. It is a just reproach to clinical medicine that so often what passes for observation is really only an "impression," and that observation, even when accurate, is not checked by a sufficient number of controls. This, however, is not the fault of the method, but of those who employ it.

Neo-Hippocratism

I have mentioned some special directions in which the observational method can still render us good service in the advance of knowledge, but, taking a wider view, I think there is reason to believe that in the immediate future still greater demands will be made upon it.

If one surveys the field of medical science to-day, and tries to estimate the direction in which the currents of contemporary thought are moving, one cannot help being impressed by the signs of a return towards the Hippocratic outlook. This new way of looking at medicine, or rather this revival, with modifications, of an old way, is called by its adherents by various names—"constitutional medicine," "the science of the individual," or "neo-humoralism," according to the element in it which seems most important to the particular observer, but it may perhaps be conveniently described as "neo-Hippocratism." The Hippocratic doctrine was founded, it will be remembered, upon the four humours and upon the *vis medicatrix naturae*, and careful clinical observation was its method of investigation. The doctrine of the humours though it dominated medicine for centuries, has long been abandoned, but neo-Hippocratic medicine deserves the title of neo-humoralism in so far as it attaches a great importance to the body fluids. It is in this respect to be regarded as a revolt against the solidism preached by Cullen in the eighteenth century, and later established on a scientific basis by the work of Virchow and of Bichat. It recognizes that all the phenomena of life are derived from physico-chemical reactions in the fluids of the body, and that a disease is often due, not, as the morbid anatomy school teaches, to the changes found in the organs after death, but rather to subtle alterations in the physical and chemical properties of the fluids, to which as one of its tasks the early recognition by biochemical the changes in the tissues are secondary; and it sets itself methods of the changes in the fluids, with a view to arresting the disease before structural modifications have taken place.

Neo-Hippocratism also attaches great value to the *vis medicatrix*. It is vitalistic as Hippocratic medicine was, and not mechanistic like the medicine of Harvey's epoch. It sees in adaptation a principle as important in biology as the principle of the conservation of energy is in physics. It regards this purposive striving of the organism to adapt itself to the environment, and to heal and restore itself when diseased, as marking off all living things from the inorganic world, and is in sympathy with Sydenham's definition of disease as "an effort of Nature, striving with all her might to restore the patient by the elimination of the morbific matter." It finds in the cause of a disease not a single agent, but a "constellation of conditions" in the environment to which the organism is seeking to adapt itself, and it attaches just as much importance to the soil as to the seed. In this, also, it is true to the Hippocratic tradition, which always regarded disease as endogenous rather than exogenous.

It lays great stress, too, on the fundamental unity of the living body, and on the interdependence or integration of its parts. It considers it to be the essential vice of specialism that it tends to concentrate attention on the parts and to ignore the whole. It holds that the very unity of the organism limits the value of the experimental method as opposed to the observational, in so far as it proceeds by an arbitrary isolation of phenomena in order to investigate them.

The circulation of the blood is, for the neo-Hippocratist, one of the chief modes by which the integration of the

body is achieved, for through the medium of the blood every cell is able to influence every other, even the most remote. Integration is also maintained by the endocrine hormones carried by the blood, and to an even greater extent by the vegetative nervous system.

Upon the degree of perfection of the integration of the individual organism thus brought about, and its constitutional balance, depends in large measure, according to this view, its capacity for adaptation, and therefore its power to resist those unfavourable conditions in the environment which make for disease. Disease is regarded as a disintegration of the organism; healing as a reintegration of it

But whilst the body is in this sense one and indivisible, it is not a mere sum of its constituent parts. The organism is more than this—it is a resultant or synthesis, *a quid novum*, which must be studied both in health and in disease as a whole This individualistic outlook is characteristic of Hippocratism, both new and old. It is, however, another plank in the neo-Hippocratic platform that whilst the human body is one and indivisible, no two human beings are alike Man is not one, but a diversity of creatures One man differs from another, not only in his inborn hereditary character, but morphologically in his "anatomical personality," functionally in his "physiological personality," and, most of all perhaps, psychologically, in his mental and nervous reactions and peculiarities Hence there arises a restoration of the idea of constitutions, which played so large a part in Hippocratic practice, and which has never entirely disappeared from medical thought It is a doctrine of constitutions, however, no longer based upon the supposititious four humours but upon measurable morphological and functional differences in individuals, and upon the results afforded by biochemistry and endocrinology.

Of the three factors which go to make up personality, or the "human biotype"—morphological, neurochemical, and psychological—by no means the least importance is attached by the adherents of neo-Hippocratism to the last. It is, indeed, one of the most significant dogmas of the school that the mental factor in disease must never be lost sight of, as it has so often been both by the "solidists" and by the exponents of "experimental medicine," but that, on the contrary, it is of the first importance to consider it in any effort to restore the whole man to health

If this is the direction in which contemporary medicine is moving, it follows, surely, that fresh demands will be made upon clinical observation, though we may have to look at our material in new ways The clinician will be restored to his pride of place, for it is he alone who can consider the patient as a whole. Clinical intuition and judgement, so often disparaged by the experimentalist, will rise again in esteem as the faculties by which alone the different factors concerned in the disintegration of the personality can be evaluated, whilst the methods of the laboratory will be reserved for confirmation and correction.

The new outlook will also demand a new anatomy—an "individual" anatomy—which will take account of the great morphological variations which may yet fall within the limits of the normal, and a new clinical physiology, which will study the functional variations in human beings and the reactions of different individuals to changes in environment. In this way the material will be gathered for what the neo-Hippocratists call "the science of the individual"

New methods of treatment also must follow, along with a reintroduction of older methods which have fallen too much into disuse. Treatment by protein shock and by blood transfusion, and a revived interest in blood-letting, are some of the results of neo-humoralism, and the employment again of what used to be called anti dyscrasic methods, and of alteratives, may follow. At all events the neo-Hippocratic attitude to disease is more hopeful than the feeling of therapeutic impotence engendered by the doctrines of the morbid anatomy school.

The Need for Bridge-makers and Generalizers

I have dwelt at some length on what appears to be the orientation of Medicine to-day and the fresh scope which it offers for observational methods, but, of course, all prophecy is vain. The invention of a new instrument, or of a new method, might suddenly do as much for medicine as the telescope did for astronomy or the introduction of logarithms for mathematics. It may be that we are on the eve of some such revolutionary development If it comes, it will probably spring from outside our own science, and from the sphere of physics or chemistry, and we may have difficulty at first in apprehending it We need, therefore, at the present day, not only observers and experimentalists, but bridge-makers, who will mediate between the laboratory and the bedside, and who will interpret and apply the work of the pure physiologist, physicist, or chemist, in so far as it bears upon practical medicine. Such men have always been few, and they must tend to get fewer as the sciences ancillary to medicine become more and more specialized; but the greater the divorce of medicine from pure science the more are such bridge-makers necessary. How they are to be found and trained, and what position they are to occupy, are questions for the future, but that men capable of acting as liaison officers in the scientific army are necessary there can be no doubt. Nor can it be doubted that they could contribute materially, if not spectacularly, to the advance of medicine.

But most of all we need thinkers. Observation and experiment can give us facts—have, indeed, given us too many facts. What we require is men with imagination, men of the contemplative type of Harvey, fertile in hypotheses, who can see the interrelation between the facts, and who can bind them into manageable sheaves and induce from them those generalizations which we call natural laws.

Great generalizers, of course, are men of genius, and cannot be produced to order They flourish in some epochs more than in others, for there are, as Bacon said, waste tracts in time as well as in space. It may be that we are in such a waste tract now Certainly men of great imaginative genius do not seem to be relatively so abundant as they were in the time of Harvey, perhaps the intellectual climate of to-day does not favour their appearance. I have already spoken of the restlessness and distractions of our day and their unfavourable effect on thought, and one might add to this obstacle the contempt for the humanities and for pure knowledge characteristic of a civilization directed to merely material ends. It may be doubted, too, whether our present methods of education are favourable to the production of men of the type we most need. To give up early the humane studies and take to specialism is not the way to train the imagination, and tends to result in the production of skilled technicians rather than of educated men. Be this as it may, there is reason to expect that the clinical atmosphere will be more favourable to the production of generalizations than that of the laboratory. For the gifts of judgement and insight, the power to see the wood and not merely the trees, so necessary for fruitful generalization, are just those required by the diagnostician. The clinical atmosphere, however, must be a wide one, for specialism is not conducive to the broad and general view.

I would conclude, Mr. President, by urging upon all the toilers in the field of medical science the necessity

r unity. We need every worker, whether at the bedde or in the laboratory, who is sincerely seeking the uth as Harvey understood it, for in the house of Science ere are many mansions. Let us not say I am of Paul, d I of Apollos, and I of Cephas ; let the experimentalist ot despise the clinical observer as superficial, nor the inician the laboratory worker as narrow ; nor let oth contemn the thinker as visionary and unpractical. et me rather exhort all, as I am bidden this day in larvey's name to exhort the Fellows of this College, that ey continue in love and affection among themselves.

TOXIC GOITRE: THE COURSE OF THE DISEASE, AND ITS TREATMENT*

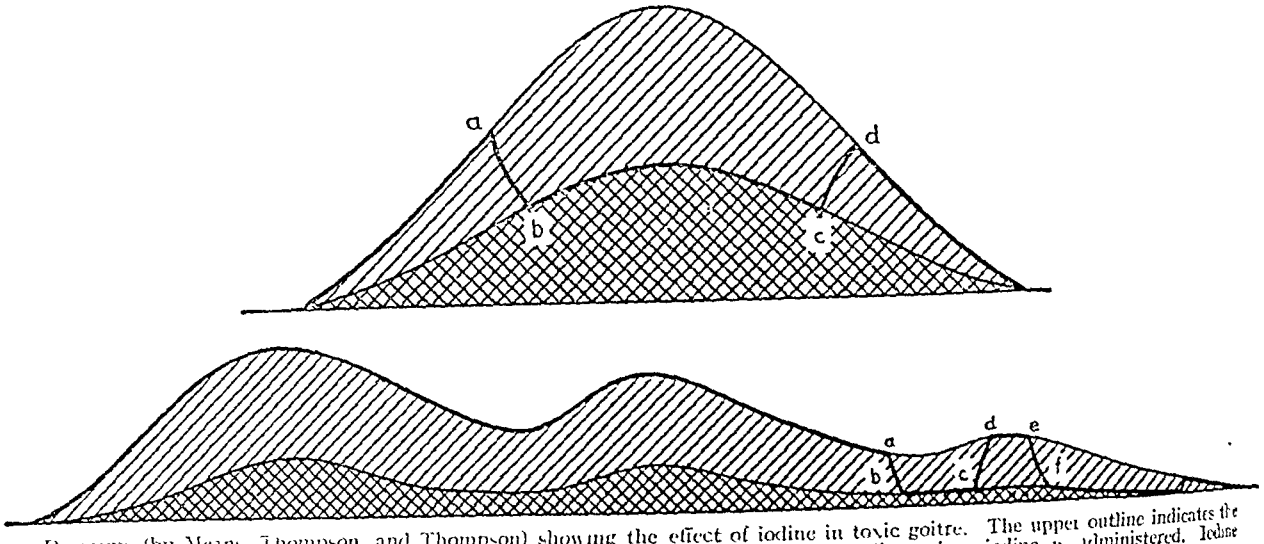
BY

F. R. FRASER, M.D., F.R.C.P.

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, AND DIRECTOR OF THE MEDICAL PROFESSORIAL UNIT ; PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON

During the last ten years, much study has been devoted o the problems of exophthalmic goitre, and much has been written on the subject. There are three lines along vhich developments have occurred that seem, especially, o have affected our conceptions of this disease and the reatment of the patients. These three lines are:—(1) the orrelation of the morbid anatomy of the thyroid gland vith the clinical conditions of the patients, (2) the therapeutic use of iodine, (3) the development of surgical reatment. The changes in the thyroid gland that ccompany the clinical conditions are very varied, and he numerous histological studies of material removed at peration, and obtained by experiments on animals, have proved of value. Following the work of Marine[1] [2] on animals, Rienhoff and Lewis,[3] working on patients, have been able to clarify this subject and to present a conception of the structural changes in the gland that can be correlated with the clinical pictures seen in patients. The relation of iodine to the pathology of toxic goitres is still unsolved, but the empirical employment of this substance in the management of cases has been a valuable step forward in treatment; and the development of surgical skill and judgement now offers possibilities of successful treatment that are among the most dramatic in medicine.

Morbid Anatomy and Symptomatology



The suggestion, made by Plummer,[4] that the cases could e divided into those of true exophthalmic goitre and hose of adenoma with hyperthyroidism or toxic adenoma, as of value in the development of our knowledge, it it now appears that this separation is arbiary and artificial, and that the changes which the yroid gland has previously undergone are the essenl factor in deciding the clinical picture and the gland icture in a case of goitre with symptoms of intoxication toxic goitre. Marine showed that increased activity the gland is accompanied by hypertrophy and hypersia, and that involution to the normal resting condition urs when the activity diminishes. Rienhoff[3] removed tions of the thyroid gland from patients who were ering from typical exophthalmic goitre, who had had previous thyroid disturbance, and who had not received line ; iodine was then administered, and at a suitable e partial thyroidectomy was performed, and the terial removed compared with that removed previous the iodine treatment. In this way he showed that the nical improvement that resulted from the iodine, the so-called iodine remission, is accompanied by an involution of the gland, a change in its structure that brought it nearer to a normal gland, but he demonstrated also that, while the gland in general showed this involutionary change, portions of it, usually lobules, might show hyper-involution, with the formation of areas of acini distended with colloid and resembling colloid goitre, or of colloid cysts, or of areas of degeneration with loss of acinar arrangement and with colloid diffused throughout the area. On the other hand, there were areas where involution failed to take place, where islands of gland remained in the stage of hypertrophy and hyperplasia typical of the condition before the remission occurred, while the surrounding gland showed the general involutionary changes and approach to the normal structure. To these islands remaining in the stage of hyperplasia he applied the term hypo-involution. Around the areas of hyper-involution the gland structures are compressed, and there is fibrous tissue giving the appearance of a capsule, formed possibly by interlobular and intralobular septums, and possibly by replacement fibrosis. These areas of hyper-involution may be single or multiple, and the gland then resembles the nodular gland, commonly found in patients of middle age with toxic goitre. These structural appearances, found by Rienhoff in the iodine remissions, are identical with those found in patients following spontaneous remissions.

There are patients, usually young women, who, with no evidence of previous thyroid trouble, develop the typical picture of exophthalmic goitre, and in the course of a few months, or longer, recover apparently completely. There are others, with a similar onset and initial recovery, who relapse, perhaps repeatedly. There are others who never quite recover, but in whom the condition subsides only to light up again and again with greater or less severity over a number of years. In those with repeated relapses or exacerbations the thyroid gland is usually found to be nodular. There are still other patients, who, when they come under observation for the first time because of toxic symptoms, present a nodular gland. We know that the gland responds to physiological stimuli, such as puberty, pregnancy and lactation, by increased activity ; and it responds in a similar way to pathological stimuli, such as infections ; but in both conditions signs of thyroid intoxication are rare, and the gland usually returns by involution to a normal condition. If the involution is not perfect, and areas of hyper-involution and of hypo-involution result on repeated occasions without the occurrence of symptoms of intoxication, then a nodular gland might be expected to develop in time. This accounts for those patients in whom such a gland is found on the first appearance of toxic phenomena. The absence of nodules and of fibrosis is not evidence that hypertrophy, hyperplasia, and involution have not occurred, but a nodular goitre is good evidence of a past history in which the thyroid gland has had to respond to stimuli and then has involuted, perhaps repeatedly and over a number of years. These nodules are not adenomas, but true adenomas may occur, though much more rarely ; and pathological processes, other than those that result from the involutionary changes described by Rienhoff, are met with in glands associated with toxic goitre, such as the small fibrous gland described by Williamson and Pearse[4] as primary arterio-capillary sclerotic goitre, and the large gland resembling that of simple colloid goitre. But an advance has been made, and we are in a better position to understand the condition of our patients.

The cause of the disease is unknown, but it cannot be doubted that there is some stimulus that causes increased activity, with hypertrophy and hyperplasia, of the gland, and manifestations of hyperthyroidism or thyroid intoxication. The stimulus, whatever it may be, will vary in

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

strength. A gland that is healthy previous to the stimulation of its activity is capable of responding with marked increase of activity, and, consequently, with manifestations of severe hyperthyroidism or intoxication; but a gland that has undergone hypertrophy and involution, perhaps many times, and that is altered in structure, with numerous areas of hyper-involution and degeneration, is not capable of reacting with the same vigour, and the degree of intoxication will therefore be less for equal degrees of stimulation. These nodular goitres are usually found in middle-aged persons, whose organs and tissues are not able to stand the stress of thyroid intoxication as can those of a young adult. Even a moderate degree of intoxication will, in the elderly, produce auricular fibrillation, though in a young girl it would only have produced a tachycardia. In the same way the vasomotor system, the digestive organs, the excretory organs, and the higher cortical functions, are profoundly disturbed in the elderly by a grade of hyper-activity that is easily borne by the young. In the elderly such stresses and strains may cause changes that overshadow the evidences of the thyroid disease, and that threaten the life of the patient. Dunhill[7] has suggested that by variations in the strength of stimulus, in the capacity of the thyroid to react, and in the state of the organs of the patient, it is possible to account for the varying symptomatology of the disease. These factors can account for many of the variations in symptoms, but there are still large gaps in our knowledge.

Diagrams (by Means, Thompson, and Thompson) showing the effect of iodine in toxic goitre. The upper outline indicates the hypothetical course of the disease when iodine is not administered, the lower outline when iodine is administered. Iodine commenced at (*a*) and (*e*), iodine stopped at (*c*).

Iodine

Since Plummer and Boothby[8] in 1923 awakened renewed and widespread interest in the subject of iodine in the treatment of thyroid disease, by pointing out its value in the pre-operative management, much work has been done, and much has been written, on this subject. We are still ignorant of the mode of its action, and there is still much controversy as to its value. There is general agreement that by its use the severity of the disease can, in many cases be profoundly lessened, and that, by administering it for a week to ten days before operation, the risks of operation are materially diminished. There is general agreement that it is not curative, and that the course of the disease is not shortened by means of it. Some observers maintain that after ten days or so it loses its effects, and that it is useless to give it for a longer period, while others believe that by its continuous administration the disease runs its course at a lower level of activity. It is difficult to reach a clear decision on these problems. There is ample evidence that the thyroid glands of fatal cases, and the glands removed at operations, contain very variable amounts of iodine[9]; and it is reasonable that the effect of iodine administration will be greater in a patient whose thyroid gland is almost completely lacking in iodine stores, and will be less striking in a patient whose gland already contains large stores of available iodine. During the course of the disease spontaneous remissions and relapses are continually occurring, and iodine cannot prevent these, though there is much to suggest that it modifies the severity of the relapses. If a relapse occurs in a patient who has been taking iodine continually for many months, and the administration of the iodine is then stopped, the severity of the relapse is immediately increased, and it is again lowered by re-administration of the iodine. The iodine content of the blood is being studied by many workers, and when the methods for its quantitative estimation are more satisfactory, so that reliable figures are available for the different phases in the course of the disease, it is possible that this subject will be clarified.

By repeated estimations of metabolic rates during iodine administration, Means, Thompson, and Thompson have come to conclusions that agree closely with our clinical experience. They say:

"In any given patient at any particular time iodine will reduce the intensity of the thyrotoxicosis, but the disease seems to continue even though in a modified form. Iodine does not reach its cause, but merely alters its effects. There seems to be a course which will be followed when iodine is supplied another when it is not."

Our practice is to give iodine continuously, and I am convinced that by it, and by rest in bed, and by the numerous other details of management, which I do not propose to enter into now, we bring our patients to a minimum of thyroid intoxication, and an optimum condition for operative treatment, at a time after the commencement of iodine treatment which may be much longer than the ten days so dogmatically stated in the literature. When operative treatment is unnecessary, iodine is one of the most valuable methods of treatment available.

Prognosis

In 1930 I published[10] an analysis of the results of treatment in 50 cases that had been carefully observed in wards during 1920-1925, and in which the results, after a period varying from five to ten years, had been obtained. The group of cases treated by operations on

roid gland and the group treated by means other than gical were roughly comparable, and it was concluded t in a number of the younger patients whose thyroid nds show no evidence of previous disease, recovery y take place without surgical treatment, but that sur- al treatment is indicated in those with nodular goitres, l in those who do not improve rapidly, or continue to apse and become chronically ill in spite of satisfactory nagement, and in those who for financial or other sons cannot submit to adequate observation and treat- nt. During the years 1926–1930 I have tried to profit the lessons of the previous period. The groups of es are, therefore, in no way comparable, as the patients re urged to submit to the treatment indicated, and ich less difficulty was experienced in obtaining consent surgical treatment than was experienced in the earlier riod. In 1931, the results of treatment were ascer- ned in 86 patients who were in the wards during the riod 1926–1930, and these are shown in the table along ch the results for the period 1920–1925.

Results of Treatment

Years.	Total No.	Surgical					Non-Surgical				
		Good	Poor	Bad	Died	Total	Good	Poor	Bad	Died	Total
1920–25	50	15	5	1	3	24	10	4	2	10	26
1926–30	86	29	15	1	3	48	13	11	1	13	38
	136	44	20	2	6	72	23	15	3	23	64

It will be seen that there is no striking difference. The ortality in those treated by operations on the thyroid nd is halved, but it is little altered in those treated by n-surgical methods. If the patient is capable of full rk, the result is classed as "good"; if working with fficulty, it is classed as "poor"; and if leading an valid life, as "bad." It will be seen that the propor- on of poor results is increased in the second period in patients treated either by surgical or by non-surgical ethods. With a few exceptions, *x* rays and radium were t employed.

Of the thirteen deaths in the group treated without erations on the thyroid gland, only one was inevitable; e patient had what were probably multiple secondary rcinomatous growths in the abdomen. One patient re- used operation and discharged herself, but had had the sease for eight years, during which treatment should ve been possible. Two others died before they could brought to a suitable condition for operation, and had en ill for 18 months and 5 months, respectively, before mission. Eight patients improved so satisfactorily that ration was not considered necessary, but they relapsed died, and in three of them the deaths followed opera- s carried out in other hospitals. In the case of the training patient, who was extremely unstable mentally, subject to repeated attacks of tetany, we did not ider that any operation on the thyroid gland was to succeed in improving the condition, but she was tted to another hospital and died, following an ation. In ten, or possibly eleven, of these thirteen , therefore, the lives of the patients might have been if treatment had been carried out earlier to diminish mount of functioning thyroid gland tissue.

h high proportion of "poor" results in the second el is to some extent due to the fact that sufficient time has not yet elapsed for the full effects of treatment tl manifest. Undoubtedly some of these results will ll be classed as "good." Even when this factor is ed for, the high proportion of "poor" results to nd" results of surgical treatment is worthy of notice.) the ca[illegible]ded into age groups, it is found that the proportion of "poor" results increases with the age of the patient; and when the cases are subdivided according to the duration of the disease before admission to hospital, it is found that the proportion of "poor" results increases with the duration of the disease. The figures are too small to be of statistical value, but the "poor" and "bad" surgical results together expressed as the percentage of surgically treated cases in the age groups 20-29, 30-39, 40-49, and 50-59, are 20 per cent., 36 per cent., 27 per cent., and 46 per cent. respectively; and in the groups with durations 1-4 years, 5-9 years, and 10 years or over, they are 31 per cent., 33 per cent., and 57 per cent. respectively. It is reasonable to expect that the older the patients the greater will be the deleterious effect of the illness on the various organs and functions, and the less likely are they to be restored to the health they previously enjoyed, but it is not fully appreciated that the longer the thyroid intoxication continues, even if it is of a very mild degree and interrupted by numerous remissions, the less likely is the patient to be restored to health.

In considering prognosis, etiology must be taken into account. The fundamental cause of the disease is unknown, but in many cases the factor that finally brings about the manifestations of thyroid intoxication is clear. In some patients it is an infection, in others mental strain and worries, in others sexual disturbances; frequently it is a combination of two or more of such factors. If the intoxication is mild and the patient is brought under medical care early, and the causal factor can be removed, there appears to be a possibility of recovery without an operation on the thyroid gland. In ten of the thirteen cases in which the results have been classed as good, and in which thyroidectomy was not performed, there was a definite association with attacks of tonsillitis, and the condition improved strikingly after tonsillectomy; they were all mild cases; the average age of the patients was 29 years, and the average duration of symptoms 2½ years. In one case appendicectomy was performed in addition, and in another, treatment with *x* rays contributed to the recovery. The longer the duration of symptoms the more difficult it is to discover a causal factor, and the factors that can be discovered are such as must be experienced by most people in the course of their lives, but the incidence of the disease is small. It is reasonable to suppose, therefore, that there is a constitutional factor. Examples of two generations being affected, and of two or more members in the second generation, are sufficiently frequent to indicate that the constitutional factor may be inherited and inborn. The following cases illustrate this:

Mrs. J., aged 62 years. Always nervous, and eyes always rather prominent. In 1918, aged 50 years, 3 years after menopause, exophthalmic goitre diagnosed. July, 1921, B.M.R. −70 per cent., partial thyroidectomy; November, 1921, B.M.R. +20 per cent., further partial thyroidectomy; June, 1922, B.M.R. +15 per cent., further partial thyroidectomy. 1931, in fair health.

Jessie J., daughter of Mrs. J., aged 31 years. Developed exophthalmic goitre in 1920, when aged 20 years. August, 1922, B.M.R. +45 per cent., partial thyroidectomy; June, 1926, further partial thyroidectomy. 1931, doing full work, tired and nervous at times.

Mary J., daughter of Mrs. J., aged 23 years. Developed exophthalmic goitre in 1926, aged 18 years. September, 1929, tonsillectomy. 1931, recovered well, now married and has a child.

J. O., aged 11 years. His mother had exophthalmic goitre when aged 17 years; she recovered without operation, but always nervous. In 1928, when aged 10 years, he developed exophthalmic goitre. October, 1929, B.M.R. +60 per cent., ligature of superior thyroid arteries; November, 1929, treatment by radium. December, 1929, died.

Warthin[11] has discussed this factor and speaks of it as the Graves' constitution, but at present it must be regarded as theoretical, because it cannot yet be recognized in the absence of the disease. It appears as if this factor is strong in some patients so that no other factor is needed to produce the disease, but that in other patients it is less strong, and in them some additional factors are necessary. The prognosis will be influenced by these considerations, and the restoration to health, even after thyroidectomy, will be less complete the stronger the constitutional factor. In some of the cases in which the result is recorded as "poor," the patients gave histories of nervousness and excitability all their lives, and appeared to have been below the normal standard of physical efficiency before the onset of symptoms of thyroid intoxication. This was clearly a factor in the results in the two following cases:

Mrs A B, aged 55 years. Nervous and excitable all her life. In 1923, aged 47 years, developed exophthalmic goitre; symptoms more severe following tonsillitis in 1922. January, 1923, tonsillectomy, continued to be nervous and excitable, and unable to do her work. April, 1928, B M R +20 per cent., very emotional and mentally depressed, and these symptoms were more prominent than those of thyroid intoxication, which were mild. April 1928, partial thyroidectomy. 1931, improved, no evidence of thyroid intoxication, but always grumbling and unhappy, and not able to do her house-work.

Miss F B, aged 46 years. Never strong, always tired, numerous fainting attacks, frequent tonsillitis. In 1905, aged 20 years, developed exophthalmic goitre, remissions and relapses frequent, and very emotional. 1926-1929, repeated attacks of tetany caused by emotion, but no disturbance of calcium metabolism, no alkalosis. July, 1926 tonsillectomy; July 1929, B M R +40 per cent., x-ray treatment; August, 1930, B M R +30 per cent., partial thyroidectomy. 1931, no tetany, but emotional storms, and unfit for any exertion.

Treatment

From the analysis of the results of treatment in the 136 patients, who have been carefully studied and followed, it seems clear that surgical treatment is indicated in most cases severe enough to be admitted to the wards of a general hospital. Of those selected as suitable for treatment without operation, nearly a third relapsed and died after discharge from hospital, so that it would appear difficult to decide when it is safe to allow such cases to return home away from close observation and experienced treatment; and the logical conclusion is that it is safer to operate at the earliest suitable opportunity than to hope for spontaneous recovery. So long as cases present themselves for treatment at the stage in the disease at which they now come to us, some means of reducing the amount of functioning thyroid tissue is necessary to save life and restore efficiency. As alternatives to surgical treatment there are x rays and radium, but both methods require such long courses of treatment, and are at present so comparatively uncertain in their results, that operation by a surgeon with special experience of operations on the thyroid gland is preferable, to save time and to avoid the risk of serious relapse during the course of radiation. Unfortunately, such surgeons, in whose hands the operative treatment has a negligible mortality, are to be found only in a few centres in this country. Even in their hands the proportion of "poor" results is greater the longer the duration of the disease and the older the patients; and it would seem unnecessary that they should be called upon, as they are at present, to perform an extremely difficult task when an earlier operation would be easier and safer, and the result for the patient would be better. If treatment by x rays or by radium were more easily controlled and more certain, these difficulties could be to a great extent avoided by commencing treatment as soon as possible after the diagnosis is made, by utilizing either x rays or radium to diminish the amount of gland tissue, by giving iodine to reduce the intoxication, and by removing any causal factors that can be discovered. If this were done while the case was mild and the patient still fit for work, the delay in obtaining the desired result, due to the longer time required by radiation as compared with operation, would not be important, and the number of late cases and severe cases, which can only be treated efficiently by means of thyroidectomy, would be so reduced that the few surgeons of sufficient experience could attend to them. Perhaps treatment by radiation is already sufficiently advanced to permit of this policy being adopted, and such treatment should certainly be tried if the case is seen early, and if the best surgical aid is not available.

Conclusions

Cases of thyroid intoxication, or toxic goitre, should be treated as early as possible by removing any causal factors that can be discovered, by the administration of iodine, and by reduction of the amount of functioning thyroid tissue. This can be accomplished with the greatest certainty by operative treatment, but if a surgeon with special skill and experience in such cases is not available, treatment by x rays or radium should be tried while the case is still mild and the patient able for work.

vironmental influences which have cramped the instinc-
ve-emotional life, with the result that the patient has
come incapable of meeting the stresses of everyday
xistence. Especially is investigation directed to the early
ife, when the seeds of a neurosis or psychosis are apt to
e sown by injudicious (though, perhaps, well-meaning)
arental handling of the child. Curiously enough, it is
ot necessarily the stern parent type which does the most
harm, but rather the over-indulgent; since the latter gives
he child an entirely wrong impression of the actualities
f life. The children of rigid Victorian parents often
merged from the ordeal of their upbringing as reasonably
djusted and efficient personalities, with an elastic and
olerant outlook.

Predisposition to Psychosis

These psychogenetic studies have both scientific and therapeutic value, and it is in no sense the purpose of this brief communication to belittle their importance. At the same time, we know that many individuals have been submitted (perhaps from early life) to conditions quite as traumatic as those which may be discovered in the history of some psychotics, without, however, exerting any notable effect upon their capacity to make a normal adjustment to life. We are thus again driven to the conclusion that there must be some predisposition in the subjects of a psychosis which renders them peculiarly liable to succumb to the inevitable stresses of life; and it is the purpose of this paper to consider, in very general terms, the nature of the defect in these patients which favours the development of a mental illness.

Psychic Pain

It is necessary to recognize that psychic pain, discomfort, or "unpleasure," is an inevitable and necessary element in life. It may, indeed, be said that consciousness came into the world as pain. In plants it is unnecessary to assume the existence of consciousness, since in these the conative impulses, which are mainly concerned with assimilating the material necessary to the metabolism of vital existence, do not take the form of seeking movements but "of a continuous appetence continually satisfied." It is otherwise in motile organisms. Writing on the psycho-physiology of hunger, Turro observes that the discomfort of hunger or thirst has for its cause the impoverishment of the internal *milieu*, and, in consequence, the distress of the cells of the organism. The internal *milieu* is not an inexhaustible storehouse; its supplies have to be continually renewed, and a time arrives when either the quality or the quantity of the internal resources is insufficient to supply the cellular avidities; the unique means, then, of repairing the deficit is to seek for the reincorporation within itself of the elements which it lacks. "At this stage," to quote Turro, "this psychic tendency, which impels to seek without what is lacking within, is what constitutes the feeling of hunger—an echo of physiological distress and, at the same time, the dawn of psychic life." Thus psychic pain or discomfort—pure feeling without cognition—is an essential, primordial, indispensable, and innate element in the process of life. It is the symbol of some physiological change within the organism, an impeded conative tendency, or an alteration in the environment, and its function is to stimulate action which will bring about a restoration of the normal equilibrium. Discomfort, and not pleasure, is the primary stimulus to vital activity. Pleasure is essentially a negative stimulus in that it either does not stimulate movements, or, if it does, only such as tend to prolong the present state of affairs. The whole of life may be described as a series of behaviour cycles, beginning, as we know, at the moment an infant is ushered into the external world, with a state of discomfort, and ending, if the actions performed are successful in furthering the conative impulses, in a state of pleasure. Such is the affective substratum of living reaction; a simple enough mechanism it would seem, but, nevertheless, it is upon its adequacy that the harmonious development of the psyche would seem to depend.

The enormous development of the intelligence and reasoning power has succeeded in opening a wide chasm between man and animals, but in spite of our impressive intellectual achievements and discoveries we have never been successful in making life an easy matter. It has merely become more complicated. No doubt human beings have more comforts, amenities, and diversions than their forefathers, but it is a pure illusion to suppose that the difficulties of life will be diminished by making it our sole concern to see that external conditions are favourable. The difficulty of life, from the amoeba up to the human being, is so obviously a constant factor, consisting as it does solely in the effort which is indispensable to being alive at all.

The Ideal Therapeutic Aim

Thus it would appear to be part of the scheme of things that life should manifest itself as a struggle to maintain, restore, and reproduce itself, in an environment which inevitably must include forces inimical to its continuance. Even supposing that external events played an important part in the causation of the psychoses, it is evident that but little could be done in the way of preventing these illnesses. It is true that psychotherapy often resolves itself into the provision of an artificial environment, in which the patient can be relieved of the inevitable tension of daily life; but this cannot be described as curative treatment. The ideal therapeutic aim is to disentangle the inner life of the patient so that he is enabled to meet the difficulties of life with confidence, courage, and good humour.

The Schizophrenic State

Unfortunately, such treatment is limited in its scope, and is inapplicable to the schizophrenic patients who comprise the majority of the chronic cases in our mental hospitals. In these patients we have an inadequate and diseased conative-affective mechanism—a mechanism which I have described above as the essential, primordial, and indispensable element of life. They are lacking, indeed, in the ability to maintain, restore, or, in many cases, to reproduce themselves—for adolescence, betrothal, marriage, or child-bearing often produces a psychosis. The picture of regression presented by a group of advanced schizophrenics is a peculiar one indeed. These patients have altogether renounced the pain and the struggle of life. They live in a world of strange fantasies, shun social contacts, are indifferent to their environment, comfort, or appearance; many have to be dressed and fed; and were it not for nursing care they would cease to exist. They live in a state of complete spiritual isolation from their fellows; they have lost all appreciation of values; for wealth, success, knowledge, art, culture and even love, mean nothing to them.

Some years ago, Jung suggested that the products of schizophrenic thought activity, so difficult to understand, so twisted and distorted, resemble very closely the normal dream activities. He expressed the view, indeed, that if the dreamer should go about performing actions we should have the clinical picture of dementia praecox. This observation is particularly interesting as recent studies at the Maudsley Hospital have led to the conclusion that the physiological condition in psychotics resembles that obtaining during sleep in the normal individual. This work was dealt with briefly in the paper by Dr Marsh. Now, however grotesque the dream, and however impressive or ridiculous the part played by the dreamer, the

latter, as far as I am aware, always remains conscious of his own identity. It would seem that the schizophrenic is in this respect much the same as the dreamer. That is to say, hidden by the delusional fantasies is the normal ego which, on occasions, is apt to reassert itself. Every psychiatrist has seen this happen when a patient is visited, in bodily illnesses, or in cases that unexpectedly recover. In these cases it is often found that the patient has an astonishing memory of all that has taken place during the period of his psychosis. It has always seemed to me to be rather curious that the highest and most recently acquired cognitive functions—mental efficiency and memory—should be preserved in these cases. One might think that, in view of educational pressure and the dreadful examinations which young people are called upon to pass, a kind of premature mental enfeeblement might result in many patients. Yet this is not the form taken by adolescent cases, many of which occur in those of brilliant intellects to whom the passing of examinations is mere child's play. What we see in our adolescent patients is not the deterioration of the most recently acquired functions, but rather of the oldest and most essential functions—namely, those of instinct and feeling, the inharmonious development of which is responsible for the symptoms exhibited.

Intellect and Instinct

It has to be recognized that intellect, as distinguished from feeling and emotion, is not an indispensable element of life. Intellect is more or less of a luxury, and a high intelligence is of less importance than a stout heart—that is to say, a vigorous, balanced, and harmonious affective life. In view of the considerable incidence of mental disorders in civilized communities, both within and outside the mental hospitals, it is perhaps justifiable to inquire whether there is not some increase in the incidence of those who are the subjects of some constitutional vitiation of the organic processes concerned with the development of the "springs of action"—that is to say, of the instinctive-emotional life.

PUERPERAL SEPSIS: THE IMPORTANCE OF EARLY TREATMENT

BY

A. REMINGTON HOBBS, M.D., M.R.C.P., M.C.O.G.

MEDICAL SUPERINTENDENT, ST. MARY ABBOTS HOSPITAL, KENSINGTON (I.C.C.); CONSULTING GYNAECOLOGIST TO THE ROYAL BOROUGH OF KENSINGTON

Anyone, seriously engaged in the study of puerperal sepsis, who possesses experience of a large number of cases, must realize the value of early treatment. The recognition of this fundamental principle in respect of other diseases—for example, appendicitis, intestinal obstruction, syphilis, and diphtheria—has been the one and only means of reducing mortality from these diseases.

In the treatment of puerperal sepsis the method of glycerin irrigation, as practised at this hospital, has been proved to be entirely harmless to living cells, and has established its claim to be regarded as the most efficient remedy at our disposal. Since this is so, why should not this method of treatment be applied at an earlier stage, in the ante-natal period for example, as well as on a larger scale at an earlier period in the puerperium, instead of postponing treatment until the uterine tissues become hopelessly infected and the blood stream invaded? The death rate from puerperal sepsis is not only practically stationary, but is far too high. Many women are left with a legacy of chronic invalidism, and swell the ranks of those who attend gynaecological clinics, when, by early and adequate treatment, any serious complication could have been prevented. Many even go into labour with sepsis already established, in spite of ante-natal care and in spite of our present-day knowledge of bacterial infections and antiseptics.

The following are the reasons, in my opinion, for the present unsatisfactory state:

1. Too much stress has been placed on the fact that the phenomena of the so-called normal puerperium are of a physiological character.

2. There is a widespread belief, unwarranted by the facts, that puerperal sepsis is always characterized by fever, the result of bacterial infection of the raw uterine surface.

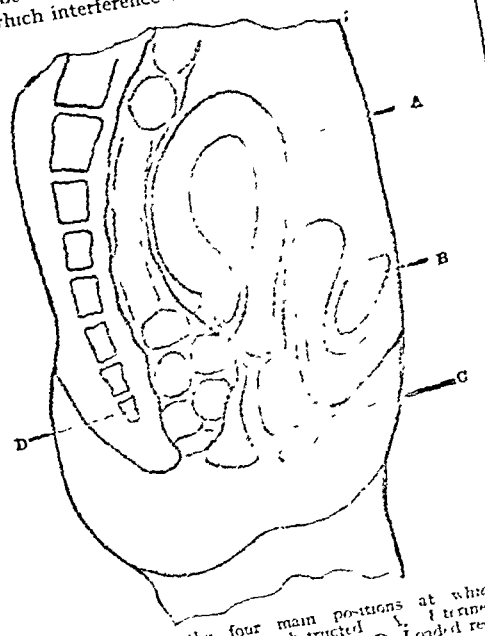
3. Treatment is in many cases not begun early enough, nor is it continued until every symptom and sign of sepsis has disappeared, and the uterus has been restored to its normal condition.

4. Most important of all, and as a corollary to No. 3, early symptoms and signs have been too long neglected by medical attendants in maternity cases.

With regard to the first reason, it must be borne in mind that after labour the raw uterine surface is an open wound; as in the case of other wounds, simple reactionary or inflammatory changes must occur in the course of healing. These reactionary changes are at a minimum in cases where the uterine surface is left perfectly clean and where it remains clean. After labour, however, placental remnants and blood clot frequently remain attached to the uterine wall, and only gradually are they extruded. So long as they remain in the uterus they are undoubtedly a potential nidus for infecting organisms of varying degrees of virulence.

The line between what may be regarded as physiological and normal on the one hand, and pathological on the other, is too fine to be drawn; the one may merge insensibly into the other. I contend that for every case of severe puerperal sepsis there are hundreds where a minor degree of sepsis exists unrecognized, but which nevertheless leads to untold suffering among women. This leads me to the second of the reasons given above—namely, that there is too widespread a belief that puerperal sepsis is always a febrile disease. Nothing could be further from the truth, and, until we rid our minds of this fallacy, little progress will be made towards combating the risks of maternity.

In every published list of statistics a temperature of 100.4° F. is regarded as the sign of puerperal sepsis. There are many instances, some to our sorrow, in which we have wasted valuable time and have exposed our patients to the greatest risk, through too blind an acceptance of this current teaching. Temperature, as an index of early pathological changes in the uterus, is by itself a thoroughly unreliable guide. All the signs of pathological inflammation must be taken into account, and, if we must take pride of place to one, surely it should be to the pulse rate.



A recent case which came under our notice will illustrate what I have just written. This patient had a normal temperature, but her pulse rate ranged from 104 to 120. At the end of four days her temperature rose to 101, and, as the standard of morbidity had been passed, active treatment was begun. The patient, however, died of septicaemia.

In my experience it is exceptional for cases of puerperal sepsis to develop pyrexia at the outset. Many patients have offensive lochia, red lochia, and purulent discharge and yet for some days remain entirely apyrexial. Further, while severe cases of puerperal inflammation are due to bacterial invasion of the raw uterine surfaces, there are a much greater number where inflammatory changes occur as a result, purely, of the retention of placental fragments

lood clot, and, as I have stated, those are the cases requently lead to chronic invalidism among women. tunately little or nothing is done at the very time much could be done, and the most favourable opportunity to deal with them is lost. Following labour or rriage, much blood and serum, together with fragof placenta, normally continue to escape from the ; for several days. Anything that interferes with atural drainage will undoubtedly give rise to signs symptoms; we must learn to recognize these, for are certainly the earliest heralds of possible trouble

A full appreciation of their significance will enable begin early and efficient treatment, by which alone n hope to reduce maternal mortality.

will be seen from the diagram there are various , at which interference with free drainage may occur.

Fetch showing the four main positions at which the ine secretions may be obstructed A. Uterine wall Cervical canal C. Swollen perineum. D. Loaded rectum

ese may be grouped under two headings: (1) intra- ne, and (2) extrauterine.

the first group the interference may occur in the is itself This may be the result of an unhealthy ition of the uterine wall antedating conception, or ıay be caused by trauma produced by the finger, ps, curette, styptics, or hot intrauterine douches. rference with free drainage may also occur owing to ruction of the cervical canal by fragments of blood and placental tissue, or by a swollen oedematous lution of its wall. Cervical obstruction is most likely ccur in the early stages of the puerperium, and calls immediate inspection. If conditions are such that rough examination is impracticable in the patient's ne, she ought to be sent to hospital without delay, ere active treatment may be begun.

Another matter that has some bearing, not only on the intenance of free drainage during the puerperium, but) on the subsequent health of the uterus, concerns position of that viscus. At the end of the first week the puerperium, when the uterus is again returning the pelvis, there is a danger of retroversion; it is im- tant, therefore, to correct this tendency by placing the ent in the prone position at frequent intervals, in ution to adopting the semi-Fowler position. Among extrauterine causes of interference with free drainage may be mentioned the following: a loaded rectum, an over-distended bladder, and oedematous vaginal walls in association with pelvic cellulitis or oedema of the perineum. The first is sufficiently obvious, and is easily remedied, but a note of warning is necessary here—the patient's symptoms may be due, not to the toxic absorption from a loaded bowel, but to interference with free escape of discharges from the uterus; in such cases special attention should be paid to measures calculated to improve subsequent free drainage. I have discussed this question, however, in greater detail in a paper read before the Royal Society of Medicine in 1924.

I have stated above that in my opinion active treatment is not begun soon enough, nor is it continued as a rule until the uterus has been restored to a perfectly healthy condition. The truth of this has been borne in upon me as the result of having had to deal with many cases admitted to hospital after the usual expectant or conservative treatment had been tried, and had been found wanting.

In cases where thorough glycerin treatment has been commenced early enough I have met with no instance where this method has failed to relieve uterine obstruction and to induce free and efficient drainage. Not only so, but during the last eighteen months, treatment at this hospital has been more thorough and prolonged, and has not ceased until the uterus has been restored to a perfectly normally functioning organ, and until all cervical erosions have been completely healed. By way of illustration I would like to mention a severe case which was recently admitted on the eighth day of the puerperium The cervix was lacerated and eroded, and there was extensive pelvic cellulitis. The patient was treated on 135 occasions, 29,450 c.cm. of glycerin being given After forty-six days the cervix had entirely healed. The detailed technique has been fully described in several previous papers.

Lastly, I would enter a plea for the recognition of the earliest symptoms and signs of puerperal disease. These have been too much neglected. It is becoming increasingly evident that every stage from pregnancy to the labour room and during the post-natal period, must be more closely watched. Actually, many women go into labour with sepsis already established. In order to minimize the risks, cervical erosions should be noted early in pregnancy, and steps be taken to treat the condition. Treatment should be carried out by regular instillations of glycerin, one inch within the cervix, throughout pregnancy, in order to reduce inflammation as much as possible. The presence of *B. coli* in the urine requires treatment in the cervical canal, and when a coliform infection of the urine exists, a similar infection will frequently be found in the lower genital tract. The treatment of both uterus and bladder, where such an infection has been present, should be actively continued during the puerperium. There is a further field for glycerin treatment in the toxaemias of pregnancy, where, after a fair trial, domiciliary treatment has failed and the patient has reached the limit of intoxication

Cases which demand treatment fall into two groups

(1) Those patients who suffer from headaches, drowsiness, oedema, increasing blood pressure and jaundice, and whose urine contains tube casts and albumin, and

(2) Those who suffer from haemorrhage

These patients should be sent into hospital early for efficient treatment Failure to do so permits progressive damage to occur in the organs, such as the kidneys and liver, and may endanger the patient's life Experience of years has taught us that the living-in ward is a surgical ward, and that it contains many cases which deviate from the normal.

What are the chief signs and symptoms which, if detected early, reduce the mortality and morbidity? They are:

(1) A temperature of 99°, and a pulse rate of 90 ;
(2) Uterine colic ; and
(3) Abnormal lochia.

With regard to the first, valuable time may be lost if the textbook standard of morbidity—namely, a temperature of 100.4°—is awaited. It is our practice to institute drainage by glycerin as soon as ever the temperature rises to 99°, or the pulse rate to 90.

Given an empty uterus, devoid of inflammation, and in good position, the patient will be free from pain. Should pain be present, a cause for it can always be found if sought for ; almost invariably that cause will be interference with free drainage. Pain is the cardinal symptom, and tenderness is the cardinal sign of an obstructed viscus, yet many medical practitioners still labour under the delusion that it is natural for a woman to suffer from after-pains for the first few days of the puerperium. These after-pains are really symptoms of a slight interference with the free escape of fluids from the uterus, and, as such, are a danger signal. If not relieved within twelve hours, active steps should be taken to encourage free drainage ; otherwise, the case may end in disaster.

The presence of offensive lochia is another indication for early treatment, especially since many of these cases do not in the early days show pyrexia. Profuse lochial discharge means, as a rule, inflammation of the uterine wall, and accordingly demands early treatment. As a general rule, it may be laid down that the red lochia should cease in a healthy woman about the sixth or seventh day, and those cases which do not conform to this rule should receive hospital treatment until all signs of inflammation have disappeared.

Early and efficient treatment along the lines that I have indicated would undoubtedly save many lives, and would lessen the number of those who frequent gynaecological out-patient clinics. It would obviate many useless curettings, and hysterectomy would be less frequent.

To illustrate the type of case in which glycerin treatment has been found valuable, I append the following figures taken from a recent six-month period. They relate to a total of 208 deliveries occurring in this hospital.

	Number of Cases	Average Number of Treatments per Patient
1 Cervical erosion	107	112
2 Secondary albuminuria	10	46
3 Bacillus coli infection	60	75
4. Ante partum haemorrhage	6	36
5. Placenta praevia	3	10
6 Internal manipulation	3	6
7. Forceps deliveries	10	8
8. Retained placenta	6	36
9 Post-partum haemorrhage	8	14
10. Retained membrane	12	18
11. Uterine colic	31	32
12 "Three nines"*	45	24
13 Offensive lochia	20	32
14 Secondary haemorrhage	20	18
15 Puerperal thrombo-phlebitis .	8	64

* Increased temperature (99° or over), increased pulse rate (90 or over).

The majority of the 208 patients suffered from more than one of the above pathological conditions. The amount of glycerin used in each case varied from a few cubic centimetres to 200 c.cm., injected once or three times daily either into the uterine cavity or cervical canal.

A recent list from the gynaecological wards over a three-month period showed that 33 patients were discharged with healed cervical erosions, the average number of glycerin treatments being 26, and the average number of days in hospital being 19.

I wish to thank Sir Almroth Wright, Dr. Leonard Colebrook, and Professor Robert Donaldson for their great help in the study of this disease, also Drs. Harold Carter, Joyce E. M. White, and Margaret E. Anderson, for assisting in the treatment.

SOME COMMON COMPLAINTS AMENABLE TO SPINAL TREATMENT

BY

THOMAS MARLIN, M.D., D.P.H., D.M.R.E.

MEDICAL OFFICER IN CHARGE OF THE MASSAGE, LIGHT, AND ELECTRO-THERAPEUTIC DEPARTMENTS, UNIVERSITY COLLEGE HOSPITAL AND HAMPSTEAD GENERAL HOSPITAL, LONDON

Any attempt to explain the benefits from spinal treatment must be highly speculative. There are many easy but incorrect explanations. We must put aside any claim that the results are due either to bone-setting or to the breaking down of adhesions. The force used in manipulation is not sufficient to break down adhesions, and there is not the resultant pain and swelling which we would expect. There are various reasons why improvements are not due to bone-setting, for here is claimed the replacement of a luxated or dislocated vertebra which was presumably impinging on a spinal nerve as it emerged through the intervertebral foramen, whereas it is well known that the spinal nerve does not fill up the whole lumen of the intervertebral foramen, but only a small proportion of it ; thus any slight mis-alignment of one vertebra is not likely to cause direct pressure on the corresponding nerve. Moreover, it ought to be possible by means of *x* rays to demonstrate not only the malposition of a vertebra, but that condition rectified after the manipulation. We have not been able to do so, and our own opinion is that there is no displacement ; but there may be a fixation or limitation of movement due to some static cause, and any sound heard during a spinal manipulation, as usually carried out, is due merely to a separation of the articular surfaces, and not to the replacement of anything that has been out of place. Indeed, in Case 1 (under Dr. McNee) *x*-ray examination was made before and immediately after the manipulation. The second series of photographs showed that the tilting had apparently been overcome. At one or two subsequent examinations the good position seemed to be maintained, but the radiologist, by making a slight change in the position of the patient, was able to reproduce in a photograph the exact tilting of the fourth lumbar vertebra which was seen at the first examination.

Luck may be a factor—the luck of some new form of treatment producing a favourable impression on the patient who returns at subsequent sittings prepared for better and better results. This factor, however, is unknown in other methods of treatment, where a psychological stimulus is used to influence physiological processes. But with the spinal treatment we are able to break into the abnormal chain of circumstances, using a physical stimulus at a definite part. When we have on the one hand some ailment or disability, and on the other hand contracted tissue giving rise to pain on pressure round particular parts of the spine, whether as a reflex from the former or whether the former is a reflex from the latter, if we are able to break in on the reflex arc, perhaps we can upset the whole

ALAWAY & PARTNERS,
BROOKMAN'S PARK STATION (L.N.E.R. main line).

nd give relief The patient's statement as to whether e is relieved cannot be proved or disproved. Neverheless, we can watch the state of the tensioned tissues the back As these become soft and loose they come less tender to touch, with possibly an abatement f the concomitant symptoms. Thus, in Case VII, with lyspepsia, from careful palpation of the back, where the only objective symptoms were available, we could feel hat the tissue tension was much less on the patient's econd and third visits, and we assumed that her lyspeptic symptoms were easier, this being confirmed by her own statement.

The essential thing seems to be to relax the tissue tension in the back. We have done it in cases similar to the above by diathermy alone and by massage alone, with the same results. The virtue of the spinal manipulation is that this relaxation is more quickly obtained. Whether ultimately it may be shown that the effects are brought about through some influence on the sympathetic nervous system is merely a suggestion. All we prefer to state at present is that we can sometimes influence certain complaints by restoring to normal some correlated tissue tension or want of mobility at certain levels of the spine.

Some Common Ailments amenable to Spinal Treatment

It can readily be understood how certain painful conditions may be affected by spinal treatment. Thus in coccydynia many patients trace the symptoms back to an accident or fall on the base of the spine, and on examination the tip of the coccyx may be found bent forward. A backward pull on the lower segment of the coccyx will often ease the condition, and I have known a patient completely cured at a single sitting after many months of misery and discomfort Sciatica and lumbago are often alleviated by manipulation of the lumbar and sacro-iliac articulations. It is possible that on occasions a sacro-iliac condition may cause a referred pain in the knee simulating internal derangement of the knee-joint. One patient, a nurse, had practically completed arrangements to enter a nursing home for removal of the internal semilunar cartilage, when her matron asked my advice A sacro iliac condition was diagnosed, and after a suitable manipulation the knee symptoms disappeared, and have not reappeared after a lapse of ten years That, however, is the only case which has ended so satisfactorily at my hands.

Passing further up, we note briefly how the stiff back following sprains or strains may be benefited by a general loosening-up of the whole spine, a procedure which is coming to be more and more practised by orthopaedic surgeons. Intercostal neuralgia may be relieved by freeing up the appropriate vertebrae and ribs, a stiff neck may call for treatment to the cervical region, and headaches associated with occipito-atlantal conditions very often clear up in a surprising manner after the joint condition has had proper attention.

Then we come to cases where the connexion between the spine and the complaint is not so apparent.

CASE I

Miss A aged 19, saw Dr J W McNee at University College Hospital for pain which warranted an *x*-ray examination of the urinary tract No calculus was discovered, but the radiologist reported from an examination of the films that there was tilting of the fourth lumbar vertebra to the left side and Dr McNee asked me to try the effect of spinal manipulation On examination, the tilting of the fourth lumbar vertebra could be felt, and there was distinct loss of motion between the fourth and fifth lumbar vertebrae. A suitable manipulation was given, and two days later the patient said she was already easier. Some gentle treatment was given that day, and after a week she said that not only was her backache better, but that the pain in her groin had gone She resumed work, but returned on three occasions for a little further treatment. Within six weeks from the commencement of treatment she was working from 9·30 *a.m.* till 9 *p.m.* without any pain; the motility of the fourth and fifth lumbar vertebrae was now well maintained, and during her last period her menstrual pains, generally severe, had been very much less in intensity.

Gynaecologists are faced daily with a very perplexing problem—the woman with pain in her back, but who at the same time has some slight deformity or displacement of the uterus. All other measures having failed, she has been sent up to have an operation on the uterus, and, if after that the backache persists, she will be labelled "neurotic" for the rest of her life. The practitioner has asked for help, and the problem is to know what to do. Some cases may benefit from an operation, but the majority of gynaecologists admit that many of them are not gynaecological cases at all. A special plea is put forward that such cases might have a trial of spinal treatment before operation is finally decided upon

CASE II

Mrs C., aged 38, under Professor F J Browne, Obstetric Unit, University College Hospital Medical School, had a history of backache for several years There was some backward displacement of the uterus, and she had been sent in to have this remedied in the hope that the backache would be cured Examination of the back showed a general stiffness of the lumbar region, and after a few treatments the backache disappeared, and she was discharged as cured

It is quite possible, though it is merely a suggestion, that spinal treatment may have some effect on the ligaments of a mal-placed uterus, or on its vascular supply in a case of enlargement, because from the following we know that profound impressions can be made on the pelvic organs

CASE III

Mrs W saw me several times during the menopause on account of severe pains and floodings Treatment was directed to the lumbar region and each time before she left the room she said that both the pain and the haemorrhage were much less In fact the haemorrhage very often stopped

CASE IV

This patient was a single lady, aged 30, who had never menstruated regularly, her last period, which was only slight, having occurred two years previously. Three treatments were given to the lumbar region, after which she wrote: "I had a successful period of five days since my last visit."

In metrorrhagia the results are most encouraging.

CASE V

Miss M. was sent up from the country for treatment for another condition, but after she started coming to me her doctor discovered that she suffered violent pains during her periods, she had suffered from the commencement of menstruation, but the pains lately were tending to become worse. It was suggested that on her next visit I might arrange at the same time to have the opinion of a gynaecologist, but after further consultation we agreed to try spinal manipulation, provided examination indicated that line of treatment Accordingly, at her next visit an endeavour was made to mobilize the whole lumbar spine there being a general rigidity in that area Within ten days she wrote "I know you will be glad to hear that I had a very good time last week practically no pain at all in the back or anywhere else I have never felt quite so well before at those times, it seems too good to be true

CASE VI

Miss B., aged 17, was sent by her mistress Her periods commenced when she was 14, occurred every fortnight or three weeks and lasted seven days She always had pain in front of the stomach on the first day of her periods. This was usually accompanied by sickness, and she had to lie down

during that day. Examination showed limitation of movement between the third and fourth lumbar vertebrae. She had two treatments at a week's interval, and when seen on the third occasion had just got over a period which, she said, was the best time she had had in her life. After two more treatments, carrying her over the next period, her mistress wrote: "I am happy to have to report about my maid that her period arrived before she got home on Wednesday. She was able to keep about that evening, and was only sick twice the next day, kept about, did her work, and ate her food apparently quite normally . . . altogether since being treated by you she has been much less moody, and much more cheerful than she has been since her periods first started—more like the happy child I first knew when she was still at school."

While dealing with the lumbar region it may be mentioned that manipulation of these vertebrae often has a very marked influence on constipation, and it is not unusual to find that people who have not had a motion for years without the use of medicine are able to return to normal habits.

Certain disorders of the alimentary tract seem to be related to the dorsal spine. For instance, there is the person who complains in a vague way of indigestion. He has pain or discomfort after food, not at any particular time after food, but he has discovered that he must be careful what he eats. He may probably say that he has no appetite or feels sick. Faddy about his food, he will not take the general run of food provided for the rest of the family. Very often he goes on a "diet," either prescribed by his medical adviser or made up by himself with the help of books and well-meaning friends. All this only goes to prove that the patient is miserable and unhappy; it does not necessarily prove that he is a neurotic subject. In such cases one often finds tenderness on either side of the spine in the mid-dorsal area, but more generally on the right side, and the corresponding vertebrae show a want of motility. Freeing up of these vertebrae may materially alter the patient's outlook and get rid of his discomfort.

Case VII

Mrs. A., aged 40, complained that for the last two years life had been a misery through sickness, loss of energy, and sleeplessness. She could not take ordinary food; in fact, she had been "put on a diet" by a physician six months previously, so she had the trouble of preparing separate food for herself and her husband. Treatment was given to overcome certain tissue tension which was discovered in the mid-dorsal region. After the second treatment she commenced to take ordinary food, and very soon resumed full ordinary diet, but said she had to avoid mutton fat. She soon gained seven pounds, slept soundly, lost her miserable feelings, and took altogether a brighter outlook on life. Instances of this nature are frequently happening.

Herpes zoster is mentioned in connexion with the dorsal region, because the only two cases I have treated were related one to the upper and the other to the mid-dorsal vertebrae. In both cases the patients were women, and the rash fully developed. They each had one treatment, and the subsequent events were similar. In each case the pain went within a few hours, and although the irritation remained they were grateful to be free from pain.

Reference ought to be made also to asthma, but, although spinal treatment often does produce a profound influence, there are many more cases where it has no effect, or at any rate produces no lasting beneficial effect.

Case VIII

Mr. S., aged 49, had been chief officer in a large liner, but was forced to give up his job on account of asthma. This was partly owing to the fact that the asthma was worse at sea, and he found that he was easier in London than elsewhere. Extreme heat or cold affected him, and he was worse at night. He had dysentery twelve years ago, which lasted five years, and then the asthma became unbearable. Nine years ago he had rheumatic fever, being in bed for three months, but had no asthma while the fever persisted. He also noticed that during bouts of malaria he had no asthma. As he took aspirin for malaria he discovered that this drug helped his asthma. It is worth noting that up to the age of 21 he was doing hard manual work as a sailor. Only after that, when he assumed the more sedentary habits of a ship's officer, did the asthma show itself. He had his first treatment on April 30th, 1930, and this was intended to loosen up the whole of his dorsal spine and free the ribs. At the same time he was encouraged to do hard work in his garden. That night he was more comfortable than he had been for a very long time. Up to the middle of May he had altogether six treatments. On October 3rd he wrote: "In reply to your inquiries I am glad to be able to say that I am very much improved in health. I have not had a single bad spell since I had your treatment, although I have had some slight attacks, which yielded readily to the simple remedy of aspirin and inhalations of burning powder. . . ." In March, 1931, he consulted me about something else, but said that his asthma was still well under control.

TWO CASES OF SARCOMA FOLLOWING KNOWN TRAUMA

BY

DAVID H. HALER, M.B., B.S.Lond.

ASSISTANT PATHOLOGIST, PRINCE OF WALES'S HOSPITAL

It is stated in Ewing's *Neoplastic Diseases* that "trauma often seems to be the sole tangible factor in originating many tumours. By trauma is here understood a single or repeated more or less contusing, crushing, or lacerating injury." Below are recorded two cases of malignant tumour formation in association with two different types of known trauma—indirect and direct. In both cases the growth proved to be sarcomatous.

The first case presents several points of considerable interest, because the patient was under continuous observation from the time of one single definite injury to the time of amputation of the affected limb. That this observation was complete may be seen from the fact that, during this period, not only was the joint *x*-rayed twice, but it was also opened and explored, and the only damaged structure therein removed. The type of growth recorded is a comparatively unusual one.

Case I

Synovial Sarcoma following Indirect Trauma

A single woman, aged 41, jumped off a chair on March 30th, 1930, and experienced for the first time an intense pain on the medial aspect of her right knee. The joint became locked in a semi-flexed position; rapid swelling of the joint ensued, and the condition was diagnosed as dislocation of the medial meniscus. This was treated by reduction and splinting. On this time the swelling was excessive, and in spite of treatment did not subside during the subsequent seven months. The joint continued to be swollen and painful, the patient was admitted to hospital, where, in view of the extent of synovitis present, extension was applied for ten days, after which the joint was opened and explored. All the internal structures were found to be normal, with the exception of the medial meniscus, which was ruptured horizontally, and was consequently removed. On examination it showed no pathological macroscopical change.

In December the patient was discharged with the note "Knee still slightly swollen."

In January, 1931, she was readmitted with increasing swelling of knee. The joint was grossly swollen, but there was no evidence of intra-articular free fluid, and the anterior patellar surface was easily palpable. A bivalved plaster was applied and the patient confined to bed. Large doses of potassium iodide had no effect on the local condition;

Wassermann reaction, the von Pirquet test, and a provocative injection of gonococcal vaccine gave negative results; there were no special alterations in the blood count.

On March 12th the *x*-ray report was: "Slight periostitis of the lower end of the femur—joint appears normal. No evidence of new growth on tibia or femur." At this time no fluid was obtained by needle exploration of the joint.

By March 20th the swelling had increased, the maximum diameter being 22 inches. A large, hard, discrete, freely movable lymph node was discovered in the right groin. In view of tentative diagnosis of sarcoma, weekly doses of deep rays were given, without avail.

On April 2nd the limb was amputated through the middle third of the femur. Convalescence up to date has been uneventful, but skiagrams of the chest show several areas suggestive of secondary deposits.

Description of Specimen.—Right lower limb amputated through middle third of femur. Knee-joint grossly swollen; overlying skin atrophic, healed operation scar visible over inner aspect; maximum diameter, 23½ inches. Patella displaced medially, softened, and extensively invaded. Joint cavity filled with a white, waxy, homogeneous growth, the limits of which are determined by a fibrous zone approximately following the distended joint capsule. The tissue is almost uniform in consistency, except for an area of hyaline-colliquative degeneration at the postero-external aspect of the lateral femoral condyle. The medial meniscus is missing, and the lateral semilunar cartilage is extensively infiltrated with growth, as are the articular cartilages—particularly in the region of the degenerate area.

Microscopical Report.—"A round and spindle-celled sarcoma of joint capsule—probably synovial in origin."

The interest of this case lies in the history of what may be termed an indirect type of trauma, the resulting symptoms of which steadily merged into those of a neoplasm, while a careful exploration of the knee-joint undertaken only four months before amputation showed no evidence of tumour formation.

The second case presents a history of the direct type of trauma, and here the symptoms of a haematoma insensibly merged into those of a sarcoma.

Case II

Sarcoma of Peroneal Intermuscular Septum following Direct Trauma

In December, 1930, a married man, aged 37, while getting on to a bus, knocked his right leg just below the knee; within two days a large, hard bruise appeared, which steadily increased in size.

In February, 1931, a piece of the tumour was removed, and on microscopical examination it was found to be a spindle-celled sarcoma.

In March, 1931, the patient was admitted to hospital with a lump about 3 by 1½ inches by 1 inch lying on the heads of the peroneal muscles and over the upper third of the shaft of the right fibula. The tumour was freely movable laterally, but not vertically. The overlying skin was reddened and bore a centrally situated recent operation scar. The lesion was not tender or hot, and there was one small gland just palpable in the corresponding groin. The tumour, together with its associated muscles, was freely excised.

Description of Specimen.—Reddish-brown tumour lying in the deep fascia, encapsulated from surrounding muscles; edges firm and well defined. No areas of haemorrhage were seen; the lump was almost entirely solid, and showed a faintly whorled cross-section. There was no apparent invasion of surrounding structures.

Microscopical Report.—"Spindle-celled sarcoma of leg, apparently arising in deep fascia not actively invading muscle; but the growth cells vary a good deal, and the tumour contains many wide vascular spaces."

I should like to acknowledge my indebtedness to Mr. R. Lyte, under whose care these patients were, for permission to publish details of their cases.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

PAIN IN THE ARM AND A DEAD TOOTH

I venture to publish the following personal experiences in case they should be of general interest.

In 1924 I began to suffer from pain in the left arm, acute enough to wake me every night during three weeks. This pain was a continuous ache deep in the arm, with tingling and numbness of all the fingers, and with exacerbations that interfered with any other activity. I could not further localize the pain, and could only compare the sensations with those in a limb that has been "asleep." I concluded that there was some disturbance of the innervation of the brachial artery. Sometimes there occurred also fibrillary spasms in the left pectoralis major muscle. I tried various remedies without success, and then had my teeth *x*-rayed in the search for a septic focus. Sure enough the first left upper molar had an apical abscess. This tooth had had the nerve removed nine years previously, and was then stopped. After its extraction the pain in the arm ceased and I ascribed it to toxic neuritis.

Five years later I had the first left upper bicuspid tooth stopped. Something went wrong, the nerve was destroyed and the roots were cleaned out and stopped, the latter process being quite painless. A few weeks later the old pain in the arm returned, and I consulted the dentist, who informed me that there was periapical inflammation around the stopped tooth. I elected to have local anaesthesia for the extraction, and he employed a "sulcus injection." As the left half of my upper lip seemed to swell up and disappear, I was astonished to find that the pain in my arm had *gone*. About twenty minutes after the extraction I tested the left half of my upper lip and found that pin-pricks were without effect until the corner of the mouth was reached, and the same held good for hot and cold sensations. Wondering if tactile anaesthesia affected the same area, I was astonished to find that I could feel the touch of cotton-wool over the whole upper lip.

I decided to look up the literature on the trigeminal nerve, and found a paper by Margaret Gerard (*Archives of Neurology and Psychiatry*, ix, 1923). According to this investigator the nerve fibres from the Gasserian ganglion enter the pons, and some end there. But a large proportion descend in the medulla and cord, and reach as far as the second cervical segment. The fibres ending in the pons are those conveying tactile sensations from the face, whereas those going down into the spinal cord convey sensations of pain and of heat and cold. Now these latter sensations were the very ones affected by the sulcus injection which abolished the pain in the arm. I then tried to find out the nerve supply to the brachial artery, but the only reference I could find in Cunningham's *Anatomy* was to a twig given to the artery by the musculocutaneous nerve from the fifth and sixth cervical segments. These segments also supplied the pectoralis major muscle. As the pieces in this puzzle fitted so well I consulted Keiller's *Anatomy of Nerve Tracts of the Brain and Cord*. Keiller states: "The sensory nuclei of the fifth nerve are connected by association fibres with the seventh and twelfth motor nuclei for face and tongue reflexes, and probably also with the motor nuclei of the brachial plexus." The pain in the arm and spasms in the pectoralis major muscle seem, therefore, to be due to long-distance disturbances from the trigeminal nerve. This would explain their localization in a way that the theory of *toxaemia* from a septic focus does not.

The phenomena suggest to my mind that disturbance in a tooth causes facial neuralgia, but that when the nerve to that tooth is destroyed then sensory stimuli from neighbouring structures can cause pain at unexpected distances from that tooth. Since the second tooth was extracted the pain in the arm has been absent.

PSEUDO HERMAPHRODITISM

The following example of an unusual condition appears to merit record

On June 14th, 1931 an Arab tribeswoman aged 25, presented herself at the Royal Hospital, Baghdad, stating that she had never menstruated and complaining of abnormal external genitalia

Examination showed the following abnormalities An ill-developed mons veneris—pubic hair of female distribution—labia majora normal—a penis with well-formed crura and glans one and three quarter inches long, projecting between nymphae which formed a prepuce open ventrally The penile external urinary meatus was deficient ventrally and its lips were continued as the well marked margins of a shallow groove which terminated at a urinary meatus of the female type in the normal position and from which she urinated Per rectum no uterus could be felt A depression, on pressure not more than 1½ inches deep, lined by mucous membrane much puckered at its extremity, represented the vagina

In general development, the patient conformed more to the male than to the female type A radiograph of the pelvis was taken by my colleague Dr A C Norman, who reports On the whole the picture of the pelvis tends to the female type, but it is not quite so open as the average female I have seen much narrower female pelves, however"

The patient volunteered the statement that for two days in each month she experienced a feeling of malaise with low backache She requested (*a*) removal of the penis, and (*b*) the formation of a vagina She has been married for four years

Laparotomy under intrathecal tutocain showed, after careful search no evidence of the presence of uterus, ovaries, or tube, either above or below the pelvic brim On the left side, just below the pelvic brim, was a well-formed testicle, the size of a large walnut, with epididymis and a vas deferens which, after a sinuous course, petered out near the bladder base These structures were all retroperitoneal, with the normal vascular connexions for a testicle in this position

The abdomen was closed and the rudimentary penis was removed with the diathermy cautery because (1) it was a useless organ which the patient stoutly affirmed never became erect during attempted coitus with her husband, and (2) under tribal conditions it would not be possible for her to change her sex She was discharged from hospital on July 3rd

It would be interesting to know how experts would classify this case I feel that some would probably be inclined to regard it as one of hypospadias in a male with non descent of the testes and cleft scrotum

I am indebted to the Inspector General of Health Services, Iraq for permission to publish this note

Reports of Societies

INDICATIONS FOR PREMATURE TERMINATION OF PREGNANCY

At a joint meeting of the Section of Obstetrics and Gynaecology with the Sections of Medicine and Psychiatry of the Royal Society of Medicine on October 16th, with Mr Bright Banister in the chair, a discussion on medical indications for the premature termination of pregnancy was opened by Dr L S T Burrell (Section of Medicine)

Dr Burrell said that he proposed to deal with indications associated with disease of the lungs Taking first the question of pulmonary tuberculosis, he thought it would be agreed that in a patient in whom the disease was arrested there could be no objection to a normal delivery at term Most people had been infected with pulmonary tuberculosis at some time, but the lesions had healed completely. Where there was liability to recurrence the problem was different The child of tuberculous parents lived in danger of infection ; he would become accustomed to periods of ill-health in one of his parents, he might be treated as a pariah by other children whose parents dreaded infection, and he would be deprived of the parental kisses and caresses which were enjoyed by the normal child But, legally, members of the medical profession were not allowed to consider the case from the child's point of view. They must only consider the effect of pregnancy on the mother In cases of acute and progressive tuberculosis of the lung he was strongly of the opinion that pregnancy should be terminated if the woman was seen before the fourth or fifth month Pregnancy was usually well tolerated by these women, but parturition was followed by a flare-up, which might end fatally If the mother survived, the disease usually became fibro-caseous, and she died within three or four years When the pregnancy had reached the fifth month it was usually as well to let the woman go to term, premature labour would do her nearly as much harm at this stage as normal delivery, and the child deserved some consideration in the circumstances With the fibro caseous type of the disease, in which the patient was just holding her own but no more, any additional stress might tip the scale against her Often women returning home from a sanatorium in this state became pregnant, and in his opinion pregnancy should be terminated in the early months in the interests of the mother But here again if pregnancy had reached the fifth month before she was seen it was just as well to let her go to term, because the shock of premature labour would be nearly as great as that of normal delivery In the chronic fibroid type of phthisis, where the disease was arrested, and where the patient showed no reaction to strain, it was justifiable to leave the pregnancy alone Where the child was not desired the parents would be inclined to urge all the arguments against pregnancy in a tuberculous woman, but if the physician felt that the case was one which he knew from experience would entail no undue risk for the mother he had no medical reason for intervention In non-tuberculous cases, such as pulmonary carcinoma, actinomycosis, and asthma, it was not usually necessary to terminate pregnancy unless the heart was failing—for example, in chronic bronchitis or asthma Pregnancy usually benefited patients with asthma, though they were made worse by parturition.

Dr T F Colton said that it was generally agreed that the primary cause of heart failure among pregnant women was mechanical, the crippled heart was unable to carry the load of the increased weight and the displacement of the diaphragm Treatment depended on the prognosis If congestive failure was anticipated, pregnancy should be terminated during the first three months Where the heart was enlarged or fibrillating during the early months of pregnancy the patient should be treated with rest and digitalis, and abortion should be induced as soon as the condition of the heart would permit In the later months of pregnancy a patient with congestive heart failure might as well be allowed to go to term, since the shock of premature labour provided the greater risk These women would stand an anaesthetic as well as non-pregnant heart cases, and the modern tendency was to feel less anxiety about anaesthesia in patients with cardiac lesions Active rheumatic infection arising during pregnancy might lead to heart failure if the infective process became quiescent, pregnancy should be terminated before the third month In women with chronic valvular disease of the heart who were not actively infected the immediate prognosis was not unfavourable and they might go through one or two pregnancies with-

affecting the course of the disease, but repeated pregnancies tended to shorten life. If increasing breathlessness of cardiac origin, or mitral stenosis with haemoptysis, or oedema had been conspicuous signs before pregnancy there was a danger of congestive failure. The tendency in recent years was to allow more heart cases to go to term, but practitioners must be vigilant for the type of woman who would be injured by pregnancy. He thought that the work of ante-natal clinics would be improved by association with the cardiac department of a hospital.

Professor Beckwith Whitehouse (Birmingham) said that there was no doubt that the induction of abortion was distasteful to most British obstetricians. In law the life or health of the mother formed the only grounds upon which labour should be induced. On a five-year basis the total number of induced abortions in eight London and provincial hospitals was only 267, an average of just over 50 yearly, or 6 per institution. On a similar basis of 16,592 private and hospital patients the number of premature terminations of pregnancy during the early months of gestation was only 112, or 0.6 per cent. Inductions of labour for pelvic disproportion were not included in this series. Was this standard of practice correct, or were obstetricians adopting an attitude which was not in the best interests of the physical and mental well-being of their patients? There could be little doubt that abortion was being induced to-day on so-called therapeutic grounds which were not regarded as indications in the generally accepted sense. He submitted figures of the indications for operation given in reports on 600 cases collected from eight London and provincial hospitals over five years. Apart from major indications, such as pulmonary tuberculosis and cardiac disease, which he left to other speakers, he drew attention to the large number of minor indications, which included rapidly repeated pregnancies; previous operations, especially on the pelvic floor; tendency to prolapse of the pelvic viscera; mental states, such as previous puerperal mania, suicidal states, and bad mental family history; general debility; asthenic states; severe anaemia. Most practitioners would agree that rapidly repeated pregnancies did not justify intervention; but were we making the fertile woman a slave to childbirth? Contraception often appeared to fail in such cases. Where there had been a previous operation each case must be decided on its merits; if the pelvic floor had been recently repaired it was certainly a temptation to terminate pregnancy. He always induced labour where the mother had a malignant neoplasm, since pregnancy exercised a stimulating effect on malignant cells. In cases of mental disease eugenic as well as therapeutic questions arose.

Mr. Eardley Holland compared a series of cases of induced labour among hospital patients with a similar series in private practice, and found the reasons for intervention to be rather different in the two groups. Among the hospital patients 65 per cent. of the pregnancies interrupted before the child was viable were terminated for cardiac disease, chronic nephritis, or pulmonary tuberculosis. Among those interrupted later in pregnancy the commonest reasons for induction or Caesarean section were albuminuria, eclampsia, chronic nephritis, cardiac disease, and diabetes. In all the hospital cases, in short, the pregnancy was terminated because labour would have been injurious to the mother. In private practice the proportion of debatable or minor indications appeared to be higher. He had performed induction on private patients for such conditions as arthritis deformans, hypothyroidism and hyperthyroidism, a history of previous eclampsia, cardiac disease, pulmonary tuberculosis, controlled diabetes mellitus, mental disturbance, and congenital syphilis with an inveterate positive Wassermann reaction; haemophilia and idiopathic epilepsy were conditions on account of which patients sometimes appealed for induction of labour. He had terminated pregnancy in a neurasthenic woman with enteroptosis whose child had recently had an unsuccessful operation for hare-lip, whose father had just died, and whose husband was leaving for India. In his experience the physician was more likely than the obstetrician to take a humane view and consider the interests of the mother, possibly because the physician had been trained to consider the patient and the obstetrician the infant. If it was impossible to guarantee that the patient was faced with no increase of risk, it was scarcely justifiable to make her go through a labour which she feared to face.

Dr. H. Yellowlees said that the psychiatrist, unlike the physician or obstetrician, had to consider the patient as a whole. It was impossible to give lists of psychiatric reasons for the induction of labour. Dr. Percy Smith, writing in the *British Medical Journal* of January 9th, 1926, had described seventeen cases in which the termination of pregnancy had been considered on mental grounds, and this might be regarded as psychiatry's classical contribution to the subject. In ten cases the decision had been in favour of induction, and in seven against, but it was not possible to define the exact grounds on which these decisions had been reached. Dr. Smith himself had said that only medical considerations should be allowed to weigh, but it was not always easy to decide which indications were purely medical. Colonel J. R. Lord, in 1927, gave the following indications for termination of pregnancy: to save life; to cure ill-health; to prevent disease. At a discussion held in Nottingham in 1928, it was agreed that termination of pregnancy seldom improved the mental state of the mother, and for that reason the psychiatrist often preferred to wait for physical indications. On the other hand, psychiatric indications were sometimes all-important; but each case must be judged individually. A speaker at the Nottingham discussion had said that eugenic data were insufficient to allow of the child being taken into consideration in deciding whether pregnancy should be terminated in a mental case.

Dr. G. W. B. James said that the course taken must depend to some extent on the mental symptoms. Termination of pregnancy was seldom justified, for example, in a case of neurosis, unless, perhaps, it was an anxiety or an obsessional neurosis. The general indications were to save life, to alleviate mental illness, or to prevent mental ill-health. If possible, the patient should be moved into hospital for observation, and he thought it was desirable that maternity hospitals should keep a room for the admission of these patients. Under hospital conditions mental symptoms often disappeared. Loss of insight was a common symptom, by which was implied the loss of the patient's hold upon reality. The fact that termination of pregnancy seldom benefited the patient's mental state might be because it was usually left too late. Psychiatry always insisted on early treatment, and this principle should be applied equally to psychoses in pregnant women. If a woman in her second pregnancy began to lose insight and to drop in weight, eventually becoming psychotic, the psychiatrist seldom demanded termination of pregnancy unless some physical indication arose. Recovery nearly always followed three or four months after labour; but was it not possible that with early termination of the pregnancy it might occur much sooner? Continental experience suggested that it would. Psychiatrists were not justified in giving a psychosis the opportunity to become fixed.

Dr. Crichton Bramwell referred again to pregnancy complicated by heart disease. He mentioned a series of eighty-two cases which had gone to term, and among

which five deaths had occurred. One of the five had died of pulmonary embolism, and the other four had been cases of auricular fibrillation. He agreed that, with cases of auricular fibrillation in which congestive heart failure was anticipated, pregnancy should be terminated if the patient was seen before the fifth month, but that after that she should be allowed to go to term. He thought Caesarean section valuable in some cases; it avoided the strain on the heart of the last month of pregnancy, and allowed of sterilization. Heart failure should always be treated and overcome before pregnancy was interfered with.

Dr. W. A Potts (Birmingham) said that at the Hallam Hospital, West Bromwich, it was possible to take patients in for observation in the way advocated by Dr. James. He believed that in a large percentage of mental cases it was possible to find septic foci which were to some extent responsible for the condition. The decision with regard to termination of pregnancy should depend on the site of such foci and the thoroughness with which they could be treated. Septic teeth, for example, should be treated early; if there was any danger that dental treatment might give rise to miscarriage it was evidently preferable that this should occur during the first few months of pregnancy. Non-specific therapy was sometimes valuable, such as T.A.B. vaccine, or, in pregnancy, an anti-streptococcal serum. It was now recognized that throat infections were allied to puerperal sepsis, and the use of such a serum might diminish the risk of puerperal sepsis later.

Dr. Percy Smith said that in his published cases, referred to by Dr. Yellowlees, the decision to terminate pregnancy had been reached after weighing the whole history. He drew attention to some of the difficulties of admitting the patient for observation under the last amendment of the Lunacy Acts. At present, unless the patient was capable of expressing herself as willing to submit to treatment, she had to be certified before she could be admitted.

Dr. B. Dunlop emphasized the importance of eugenic considerations, which, he said, had received little attention during the discussion. If there was good reason to suppose that the child would be defective it could not be regarded as justifiable to allow it to be born. He referred to a paste now widely used in Germany and Russia to procure abortion, and anticipated an increase in the number of abortions once its use became generally known.

Dr. Leonard Findlay agreed that the child had come in for little consideration during the discussion. As a paediatrician he thought it calamitous to allow the birth of the child where the mother was suffering from active pulmonary tuberculosis. He was surprised that Mr. Eardley Holland should regard an inveterate Wassermann reaction as grounds for the termination of pregnancy where the patient was a congenital syphilitic. He had never heard of a third generation transmission of the spirochaete. He considered deaf-mutism of one or both parents to be a far more serious indication for intervention, and a family history of haemophilia was another sound reason. The method of choice was Caesarean section with sterilization. Mental deficiency was not usually inherited, and it was rare to get more than one case of mental deficiency in a family, except with certain familial degenerations.

Dr. E. Stolkind said that he knew of no diseases due to septic teeth, and that far too many teeth were taken out at the present time. Women who did not wish to have children frequently went abroad for induction of labour, and many of them were really ill, and had been advised to have no more children. He did not believe that it was ever possible to say when pulmonary tuberculosis was quiescent; there was always a liability to relapse, and women with this disease should be helped to avoid pregnancy.

In replying, Professor Whitehouse said he had found that if a pregnant woman with early psychotic symptoms was threatened with a visit to a psychiatrist the symptoms often cleared up.

THE DOCTOR IN WAR

At a meeting of the United Services Section of the Royal Society of Medicine on October 12th, the presidential address was delivered by Lieut.-Colonel E. M. Cowell, D.S.O., the first Territorial Army medical officer to be elected to the presidency. Colonel Cowell devoted the first part of his address to a brief history of military surgery, and afterwards proceeded to speak of a recent departure in connexion with air ambulance units.

In the historical part he said that in ancient Egypt the military surgeon was held in high esteem, less so in ancient Greece, though Hippocrates advised those who desired to become surgeons to join the army and follow it. In the Roman Army Julius Caesar bestowed the rights of citizenship upon his doctors. It appeared that Roman naval surgeons received double pay as a special inducement to enter that service, for the Romans hated the sea. In the Eastern Roman Empire, where army organization reached a high level, medical corps were established. In feudal times in Europe nothing was done for the common soldier. The Crusades did not contribute to any extent to the advancement of military medical science, but Colonel Cowell indicated a few landmarks in history, such as the establishment of the Order of the Knights of St. John at the end of the eleventh century, the accompaniment of Edward I by a number of medical men on his invasion of Scotland, the establishment of military hospitals in France in the sixteenth century, the mention of a hospital ship at the time of the Spanish Armada, the improvements in the service in France under the stimulus of Cardinal Richelieu, and the fact that in seventeenth century England Thomas Willis, William Harvey, and Richard Wiseman were surgeons to the army, and at a later time Percivall Pott and John Hunter—the latter, though brilliant as a surgeon, not a success as a military administrator. The speaker, with a mastery of compression, carried on the story to the Franco-Prussian war. He then added a few words on military nursing, mentioning the women who rendered aid to military heroes in Homer's *Iliad*, the Order of the Sisters of Charity, founded in the Thirty Years' War, and, finally, the magnificent work of Florence Nightingale.

Air Ambulance Units

In the second part of his address Colonel Cowell spoke on the question of air ambulance. Recently, he said, the Order of St. John and the British Red Cross had taken up this matter, and air ambulance detachments were being formed under that organization. The first machine—a Desoutter monoplane—had been presented anonymously to the Surrey Branch of the British Red Cross Society, and was established at Croydon aerodrome. It was capable of taking two lying cases or one lying and one sitting case, and the operation of loading, through the port window, could be very expeditiously performed in forty-five seconds. It was a very comfortable machine, entirely enclosed, and, in the speaker's view, compared very favourably with the "avions sanitaires" which he saw on attending an air ambulance demonstration in Paris at the end of July. One of these was just capable of carrying one stretcher, and the poor patient had about as much room as if he were in his coffin.

Offices: BROOKMAN'S PARK STATION (L.N.E.R. main line). Tavistock Square, W.C.1.

Colonel Cowell concluded with a cinematograph demonstration illustrating the Desoutter monoplane at Croydon—loading, taking off, and landing. It was shown making its first flight with the Red Cross mark on June 4th of this year. It was able to achieve a speed of 120 miles per hour, and could take off and land in as little space as any other light aeroplane. It resembled the two-seater Ford ambulance car, which was so useful in the war. He added that the ambulance machine was available to transport civil cases to and from any place at any time.[1]

Air Vice-Marshal J. McINTYRE (Director of the Royal Air Force Medical Service) congratulated Colonel Cowell on a most interesting address. The evacuation of sick and wounded by the Air Force had so far been limited to Eastern countries, where ordinary means of transport scarcely existed. There was no special Air Force ambulance. What was used in a big evacuation was a large troop carrying machine, which conveyed the sick and wounded—principally the sick—over considerable distances. Otherwise small general purpose machines were employed, capable of carrying one stretcher case, and perhaps one or two sitting cases. Certain types of machines had spares which enabled them to be fitted to take stretchers. Another method by which sick had been evacuated was by strapping them on the top of the fuselage, but that was not a device which he favoured.

Lieut.-General Sir H. B. FAWCUS (Director-General A.M.S.) gave it as his opinion that air ambulance transport in the next war, whenever it might come, would be an absolute necessity. He was certain that the method on which Colonel Cowell had been working was one which was likely to ensure air ambulance transport at the beginning of a war. Before the last war, in 1913, there was a strong movement to get motor ambulances for work in the field, but no success was forthcoming. The war had not been going on for very long, however, before it became most evidently necessary to have motor ambulances, and these were obtained without difficulty and in very large numbers. He was sure that if the country went to war again without air ambulance transport, there would be the same outcry, the same necessity, and the same result.

Surgeon Vice-Admiral BOND (Medical Director-General R.N.) proposed a vote of thanks to Colonel Cowell, which was heartily accorded.

[1] Inquiries should be addressed to the Air Ministry, any air transport agency, or the Rollason Aviation Company, Croydon Air Port.

INDIVIDUAL PSYCHOLOGY AND THE SYMPATHETIC MECHANISM

At the first meeting of the session of the Medical Society of Individual Psychology, on October 16th, Dr. W. LANGDON BROWN delivered the annual address from the chair. It was reported that the membership of the society had risen to fifty during its inaugural year.

Dr. Langdon Brown prefaced his address by explaining that he was not a trained psychologist; he had been brought up in an entirely materialistic school of medicine, but having started by applying physiological principles, he was forced by the logic of necessity to pay regard to the underlying psychology. He considered that a striking feature of twentieth century medicine was a return to the cult of Aesculapius, which might be summed up as baths, fresh air, dream analysis, and psychological explanation. A very important part of treatment under the ancient cult was the interpretation of dreams by priests, and from this there developed a more or less definite psychotherapy. No doubt dreams did sometimes, to those who watched them carefully, betray the condition of the body. There was much in the temple ritual which might seem like quackery to-day, but he would prefer to call it psychotherapy adapted to the needs of former times. After all, reason was a more recent human acquisition than the emotions, and our forefathers for thousands of years depended for healing on magic alone. For himself the significance of this modern return to Aesculapius was the recognition of the importance, not only of the disease from which the patient suffered, but of the patient who suffered from the disease, together with his reactions, his environment, and his hereditary tendencies. It was by the combined attack on the physical and psychological side that medicine would make advances in the future. So far medicine had given scant consideration to the way in which man adapted himself to the social environment; and, after all, man entered this world much more completely equipped to deal with the life of internal relations than to deal with environment.

Passing on to speak in particular of the work of the late W. H. R. Rivers, to whom he paid a high tribute, Dr. Langdon Brown said that Rivers had extended the work of Hughlings Jackson, who described three levels of the nervous system—the reflex, the sensory and motor, and the psychological—as representing three successive stages in development. Rivers postulated a number of different layers within the highest level. The development of the individual mind, he considered, led to the formation of consecutive layers, indicative of increasing reality and self-control, but each individual started out equipped in the lower levels with earlier racial tendencies held more or less in abeyance by the higher levels. The control of the higher levels in dreams and in disease was lessened, and the older and more primitive methods of thought reasserted themselves. Thus one could see how easy it was for a sick person to believe in magic. Rivers considered that a mental event could be relegated to the unconscious either by a conscious act of volition or by an unwitting suppression. The latter he regarded as a normal incident in development. Thus the higher levels of the nervous system were reached on the stepping-stones, not only of our dead selves, but of our long dead ancestors. It was clear that the nervous system originated before anything which could be called consciousness appeared, and that the sympathetic nervous system worked quite apart from consciousness, remaining for ever beyond the control of the will. It retained certain features of the primitive nervous system, both in structure and in function. The effects of sympathetic stimulation were all designed to activate the body for a struggle and increase its power of defence, while parasympathetic stimulation in general replaced the display of kinetic energy by the storage of potential energy. The sympathetic was katabolic, directing the stream of energy outwards; the parasympathetic anabolic, directing it inwards. When these were distributed to the same structures their actions were always antagonistic. When the one was stimulated the other was inhibited, and the rhythm of life depended upon the balance between the two. The predominance of the parasympathetic in sleep was further shown by the occurrence of "accidents," such as asthma, enuresis, and emissions. It might be asked on this theory how to account for the parasympathetic effects that were seen in overwhelming pain and fear, such as collapse, syncope, and loss of sphincter control. Rivers had pointed out that the lowly organism possessed another method of defence—namely, immobility—which took the form in some animals of shamming death, and might prevent detection by foes. These two reactions—on the one hand immobility, and on the other preparation for fight or flight—obviously admitted of no compromise. To attempt to combine the two would be fatal. If one of them prevailed, the opposite group

was inhibited. The sympathetic co-operated with the adrenals, the thyroid, and the pituitary; the parasympathetic with the glands of the digestive organs and their annexes, and possibly with the parathyroid.

Dr. Langdon Brown went on to emphasize the importance of recent work on the close association between the pituitary, which was the leader of the "endocrine orchestra," and the hypothalamus lying immediately above it. Cushing had said that no other single structure of the body was so deeply protected, centrally placed, and well hidden as the pituitary. Here was the mainspring of primitive existence—vegetative, emotional, and reproductive—on which, with more or less success, man had come to superimpose a cortex of inhibitions. It was abundantly clear that however the sympathetic nervous system was brought into action, it stimulated the expression of certain emotions, preeminently fear, with tachycardia, sweating, blanched extremities, and the like. Psychoneuroses might express themselves at any one of the three levels: at the psychical level as an obsession; at the sensory motor level as a paralysis, contracture, tic, or anaesthesia; and at the visceral level as various vegetative neuroses. The state of continued fear, whether recognized or not as such by the sufferers, was capable of producing the symptoms of which they generally complained. Sympathetic irritation by stimulating the mesenteric nerves might inhibit peristalsis and cause intestinal stasis. Therefore an adequate rationale for existence, whether a happy marriage, an absorbing profession, or even a political agitation, might have remarkable effect on the symptoms of visceroptosis.

In the concluding part of his address, Dr. Langdon Brown took as an illustration and gave a striking analysis of the life and writings of the late D. H. Lawrence. He noted that one literary critic had declared that Lawrence's influence upon the younger generation would be overpowering, but Dr. Langdon Brown doubted this. Lawrence had great literary gifts which were fatally crippled by a psychoneurosis, and, to a generation of minds undamaged by the war and by the scarcely less disastrous peace that followed it, he should be given no more than his proper place. In his closing passage Dr. Langdon Brown said that Sir James Mackenzie had defined symptoms as the disturbance of normal reflexes. A normal reflex was certainly purposive, and should be painless. Through a chain of conditioned reflexes man associated ideas and achieved consciousness. This consciousness appreciated that a disturbance of the normal reflex was painful, and, being still purposive, proceeded to investigate the cause of the pain. The dog licked his bite, the burnt child dreaded fire, but from such simple defensive reflexes as these were built up elaborate associations of ideas until, in the process of social evolution, certain individuals became set apart to be epicritic on other people's protopathic sensations, and to try and rectify these disturbed and therefore painful reflexes. "There is thus no break in the chain between simple reflexes and the evolution of the medical profession. Behold us here assembled as the last link in a long chain of conditioned reflexes!"

Dr. F. G. Crookshank, in proposing a vote of thanks to Dr. Langdon Brown, said that the address had united a broad humanity with a wealth of clinical interest and scientific knowledge. If there was one danger which attended the growth of individual psychology it was that in their observations of psychological mechanisms they might be a little oblivious concerning the sympathetic and other mechanisms. By his analysis of the case of D. H. Lawrence, Dr. Langdon Brown had shown how perfectly the philosophy of Adler illustrated that strange life story.

VOLUNTARY EUTHANASIA

The annual general meeting of the Society of Medical Officers of Health was held on October 16th, when Dr. C. Killick Millard, medical officer of health for the city of Leicester, was installed president. Dr. Millard immediately proceeded to deliver his presidential address, the unusual theme of which was "The legalization of voluntary euthanasia." He prefaced it by saying that he had been surprised to learn how much agreement there was on the subject in the medical profession and outside, and he read endorsements which he had received from some medical men in Leicester and elsewhere to the effect that the principle underlying the practice of euthanasia was ethically sound. He also coined an epigram which he placed at the forefront of his address: "The great task of medicine is to prevent disease, and, failing that, to cure disease. If it fails in both, science, at least, enables us to shorten the sufferings caused by disease."

Vast numbers of human beings, said Dr. Millard, were condemned to end their earthly existence by a lingering, painful, and often agonizing form of death. Much of the "sting of death" lay in the prolonged physical suffering which preceded it; death itself was regarded by both patients and friends as a "happy release." The serious increase during recent years of mortality from cancer had definitely increased the proportion of painful deaths. Voluntary euthanasia, the subject of his address, excluded everything save euthanasia which was desired by the person concerned; he was not proposing that imbeciles and mental defectives should be painlessly deprived of life, that old people who had become a burden to their relatives should be quietly sent to the lethal chamber, or that anyone who wished to do so should be allowed, still less encouraged, to commit suicide. His proposition merely was that individuals who had attained to years of discretion, and were suffering from an incurable, fatal, and painful disease, should be allowed by law, if they so desired and if they had complied with the requisite conditions, to substitute for the slow and painful death a quick and painless one. This should be regarded, not merely as an act of mercy, but as a matter of elementary human right. It was conceded already in the case of animals, and neglect to "put the poor creature out of its pain" would be regarded as actual cruelty.

The proposal was not new. In Sir Thomas More's *Utopia* euthanasia was encouraged in the case of those suffering from an incurable disease. Many of the ancient philosophers were definitely in favour of it. Pliny, for example, declared that it was one of the greatest proofs of the bounty of Providence that it had filled the world with herbs by which the weary might find a rapid and painless death. Dr. Millard was at pains to distinguish between legalized voluntary euthanasia and suicide. The difference was as real as between the sacrifice of life for one's friends and suicide as a means of escape from difficulties, or between killing in war and private murder. He discussed the views as to suicide held by primitive and more advanced peoples, as well as the strongly antagonistic attitude of Christianity, which was reflected in secular law, where suicide was still regarded as a felony. But he quoted the present Dean of St. Paul's (*Christian Ethics and Modern Problems*):

"It seems anomalous that a man may be punished for cruelty if he does not put a horse or a dog 'out of its misery,' but is liable to be hanged for murder if he helps a cancer patient to an overdose of morphine. . . . I confess that in this instance I cannot resist the arguments for a modification of the traditional Christian law which absolutely prohibits suicide in all circumstances."

The ethics of suicide, in Dr. Millard's view, depended almost entirely upon the motive prompting the act, and

pity rather than censure should be the predominant sentiment in certain cases But legalized voluntary euthanasia would come into quite a different category as an act which was rational, courageous, and often highly altruistic Dr Millard had drafted a Bill to make voluntary euthanasia legal A person desiring euthanasia would make an application stating that he had been informed by two medical practitioners that he was suffering from a fatal and incurable disease as defined in the Act and that the process of death was likely to be protracted and painful He would also state that his affairs were in order, that his near relatives had been informed, and that he knew of no valid reason why he should not be granted the necessary certificate This application would be duly attested by a magistrate, and accompanied by two medical certificates—one from the regular attendant, and the other from an independent practitioner The application and certificates would be sent to an official appointed for the purpose who would satisfy himself that all was in order The case would then come before a court of summary jurisdiction at which any objections would be heard, and the court if satisfied, would issue the necessary permits, one to the applicant to receive euthanasia, and the other to a medical practitioner to administer it Only practitioners licensed for the purpose would be eligible as euthanisors " The procedure would be governed by regulations made by the Home Secretary or Minister of Health The usual method would be to swallow a narcotic draught, and a prescribed procedure would be followed, or, in cases where the patient was unable to swallow, the lethal dose could be administered hypodermically An independent and official witness would need to be present and to countersign the certificate which would be filled up and signed by the euthanisor Dr Millard admitted that the number of persons at first who would take advantage of the Act was likely to be very small, but by degrees as people became accustomed to the idea, the numbers would increase Doubtless as in the case of cremation, the movement would be helped by the example of a few outstanding men and women He discussed the ethical practical and legal objections and in particular the precautions which would have to be taken to prevent possible abuse relating to life insurance He protested that his suggestions should not be regarded as Utopian in view of the drastic and revolutionary changes which had come about during recent years, such as the innovation of summer time the legalization of cremation and the toleration of birth control

The vote of thanks to the president was proposed and seconded respectively by Professor Bostock Hill and Dr Charles Porter the former remarking that he was glad, on the whole that it was not the rule to discuss presidential addresses

Reviews

COMMON DISEASES OF THE NERVOUS SYSTEM

Dr T J Nattrass is to be congratulated on producing a very readable book, *The Commoner Nervous Diseases*[1] It is described as for general practitioners and students, and should prove extremely useful to both classes of readers His first chapter deals with the examination of the patient, and is a model of clearness and orderly thinking It cannot be too strongly emphasized that the same scheme of examination should be rigidly adhered to in every case it is only by such work that students can hope to make themselves scientific members of the profession In his chapter on disseminated sclerosis the author refers to a toxin destroying the myelin sheath, he might have mentioned that this is probably a lipase, and that its action might be inhibited by quinine It is rather doubtful if the theory that spirochaetes in the aorta exert a toxic effect in tabes dorsalis is to be taken seriously—fully 85 per cent of general paralytics show a syphilitic aortitis without necessarily showing tabetic symptoms We are glad to see the appearance of a loss of sensation on the centre of the face given as an early sign of tabes, because this is not sufficiently widely known When dealing with the treatment of dementia paralytica, reference might with advantage have been made to tryparsamide, the results of which are every bit as good as those with malaria, and the mortality practically nil With malaria there is nearly always in any series a mortality of about 10 per cent The more recent treatment by diathermy we think merits a trial for it is easily controlled and secures high temperatures

The chapter on epilepsy is well done, it is admittedly difficult to discuss such a big subject as the etiology of the epilepsies in a page or two The author does not emphasize that epilepsy commencing after the age of 30 is almost invariably organic and not idiopathic We would have liked to see some mention of both dehydration and the ketogenic diet in the treatment of epilepsy The latter has been shown to be of great use in children and adolescents, and it is at this stage that treatment, if it is going to be of any value, must be instituted Vascular lesions of the brain are very well dealt with The chapter on epidemic encephalitis emphasizes the profound difference between the mental sequelae in children and in adults In discussing migraine, the author might perhaps have mentioned the interesting fact that approximately 60 per cent of epileptics have a migrainous heredity, compared with 17 per cent among normal people Only 14 per cent of epileptics have an epileptic heredity, whereas 7 per cent of normal people have It is questionable whether a short chapter devoted to the psychoneuroses in a book of this character serves any useful purpose Practitioners assuredly want a more detailed account of these conditions than Dr Nattrass supplies We are inclined to think that the term ' minor psychoses ' might be used instead of ' psychoneuroses ' and the term " neurasthenia " quietly abandoned Such a variety of ill defined conditions are grouped together under the heading that it has ceased to have any real use apart, perhaps, from the sense in which Freud uses it These, however are criticisms of what are really small points The author has done his work well and the production of the book reaches the high standard we always expect from the Oxford Medical Publication-

DISEASES OF CHILDREN

Several new foreign works dealing with various aspects of diseases of children may conveniently be reviewed together. The most recent addition to the Monographs on Paediatrics Series is by Professor M. Metzger and Dr. A. Héraux, and covers the first days of the newly born.[2] The preliminary sections deal with the general hygiene of the normal newborn infant, with very practical details for management and feeding, and the special cases of the underweight baby, the overweight baby, and the Caesarean baby receive careful attention. The second half of the book gives an account of the disorders of the infant in the first few months of life, under the main headings of gross syndromes, infections, haemorrhages, birth injuries, and malformations, while a very good section is included on the clinical manifestations in the infant resulting from various disorders in the mother. The authors have also added a series of forty clinical records, illustrating various points brought out in the course of the book, and these are a valuable addition to a volume which, even without them, is packed with useful information and practical advice.

Professor J. Cathala, in his Pathology of the Infant,[3] covers the same period in the life of the child, but his book is addressed mainly to students at the beginning of their work in a paediatric department, and is necessarily more elementary and much briefer. The title is in many ways a misnomer, for, although diseases of the newly born are considered from the aspect of departure from the normal physiology of this period of life, the author also deals with clinical features, such as the physical examination, signs, and symptoms, and concludes with a short chapter on treatment on very general lines. As an introduction to the study of paediatrics, however, this small volume can be recommended, and the English medical student might well attempt the very straightforward French in which it is written.

With Professor P. Nobécourt's latest addition to the series he is publishing, dealing in this new work with affections of the haemo-lymphopoietic organs and of the blood,[4] the reader comes upon a typical French monograph. Here are the author's clinical lectures arranged so as to deal with the subject in a systematic manner without necessarily covering the whole ground. Each chapter is based upon a definite case or cases, and the substitution of the written for the spoken presentation is associated with an abundance of illustrations, both of patients and of charts. The main parts of the book deal with three themes—anaemia, purpura, and glandular enlargement—and from these main presenting signs the author develops the finer classification to embrace leukaemia, the haemorrhagic diseases, lymphadenoma, etc. The clinical descriptions, the carefully indicated steps in diagnosis, the detailed information about treatment, and the discussion of etiology and prognosis are all achieved in the masterly manner which is now well recognized as an essential feature of Professor Nobécourt's contributions to this branch of medicine. He makes no claim to have solved many of the problems which still exist in regard to the blood disorders of childhood, and yet the solution of such problems undoubtedly lies in such a volume as this, packed from start to finish with personal observations of carefully studied clinical material. The index is surprisingly good when one remembers that French publications so often neglect this important feature; in the other two books mentioned above the index could be greatly improved.

The last member of this group comes from Germany, Dr. W. Pflüger contributing the seventh and final volume of the large work on practical differential diagnosis, edited by the late Professor G. Honigmann, under the title of Differential Diagnosis in Paediatrics.[5] The subject is considered along the usual lines, beginning with the newly born and the infant, and thus on to the small child and the older child. For the most part the sections deal with various leading symptoms and signs, such as vomiting, jaundice, convulsions, etc., and the concluding chapters on the specific fevers are particularly good. The absence of any illustrations is a serious drawback, and even without this disadvantage it is doubtful whether the book can bear comparison with the well-known work by Feer on the same subject, in the same language. The general production is otherwise good, the print clear, and the index very good.

A SURVEY OF PHARMACOLOGICAL PROGRESS

Recent Problems in Pharmacology,[6] an amplification of the textbooks, by Professor Hans Handovsky, is the twenty-fifth of a series of volumes on recent scientific progress appearing under the editorship of Professor Liesegang. The author has aimed at giving an account of pharmacological progress during the years 1914–29. He estimates that the pharmacological literature during this period amounted to 90,000 publications, and out of this overwhelming mass of material he has selected 1,636 references. The text of the work only occupies 188 pages. These figures indicate that the author has expended a very great amount of labour in the preparation of his volume, and that the material has been rigorously sifted. Closer study confirms these impressions, for an examination of the references shows that they are remarkably complete, and that they have been chosen in an unbiased manner from the literature of all countries. The text is so condensed that it makes difficult reading, but as the volume supplies pointers to all important recent work it will prove a very valuable work of reference for pharmacologists. The author has treated his subject from the functional point of view, and deals in turn with the pharmacology of different systems. Thus the titles of some of the earlier chapters are: "Pharmacology of energy exchange," "Pharmacology of the metabolism of water and of ions," and "Pharmacology of the autonomic nervous system." It is impossible to give any short account of the contents of a book such as this, which is an example of extreme compression. The author has covered an enormous field, and has summarized all the most important recent advances in pharmacology. It is the kind of summary that could only be compiled by an author outstanding both for his industry and for his learning.

VOCATIONAL GUIDANCE

Not very long ago it would have been true to say that the choice of an occupation or a career for a boy or girl leaving school was almost entirely haphazard. For some years past, however, a good deal of trouble has been taken by, or on behalf of, local education authorities,

associations of teachers, the Ministry of Labour, and by individual head masters and head mistresses, in the placing of school-leavers in what are believed to be appropriate posts. Local authorities have, in fact, been empowered by legislation to organize such assistance to boys and girls since the year 1910, and much has been done by some of the larger authorities, and considerable success has been achieved. Latterly, the aid of the National Institute of Industrial Psychology has been increasingly sought in these efforts; and a great deal of information about the work of this institute in the direction indicated is to be found in a volume entitled *Methods of Choosing a Career*,[1] by Mr. F. M. Earle, and some other members of the staff of the institute. There is a preface by Dr. Charles S. Myers, the principal, and a foreword by Lord D'Abernon, the president, who remarks that "a vast number of young people tumble into their occupations by chance, instead of being guided into them on grounds of suitability, and that many of these, year in and year out, are doing work for which they are not naturally fitted. To the community this represents an incalculable loss in efficient service; to the individuals concerned it means needless discontent, irritation, and strain." Any attempt, therefore, to estimate the value, and improve the methods, of vocational psychology in determining the occupations best suited to adolescents is of great interest and public importance.

The book has been planned so as to be valuable both to the cultured layman and to the psychological expert. It is a full study of an experiment rendered possible by the benevolence of the Carnegie United Kingdom Trust, in the course of which six hundred boys and girls leaving the elementary schools in a certain part of London were given advice by the institute as to their occupation in life, the results being followed up over a maximum period of four years. There was a control group of the same number, where careers were similarly followed up, but who had merely received the ordinary, but careful, advice often given by the education and employment authorities in such circumstances, without the help of the institute. The difficulties of conducting such an experiment, and the allowances that have to be made for disturbing factors at every stage, must be apparent. A perusal of this book will make it evident that they were greater even than might have been supposed. Yet the results obtained were extremely encouraging, and fully justify the tentative submission, in an appendix, of a working plan for the establishment of a general scheme of vocational guidance on the lines adopted in this experiment. The co-operation of many persons is necessary, and not the least essential of these is the school or private doctor. "The importance of an adequate medical examination is indicated by the fact that about 15 per cent. of the children examined by the institute proved to be aiming at occupations for which they were unsuited on medical grounds." The school doctor is, of course, primarily concerned only with ensuring that the physically unfit child receives treatment, but his position with regard to vocational guidance is bound to become increasingly recognized, and, indeed, in Brussels he is definitely used in this connexion.

The aims of the experiment and its scheme in general are first described, then the different methods of examination, of formulating advice on the basis of the information obtained, and of conveying this advice to parents and children. Some of the details given are of the utmost interest and value. The book then goes on to refer to the study of the occupations which present themselves, and sets out the nature and methods of the study of the after-careers of the children, both of those who had received or had not received the institute's advice, and of those who had or had not followed the advice so given. The general results of this following up are described, and the data are elaborately analysed. The analysis takes two forms: one the form of case study, which will certainly be most instructive to the non-expert reader; the other the form of statistical tables which are intended primarily for the detailed consideration of the technical expert. In a final chapter the whole experiment is reviewed, and some indication given of its great practical value, and of the ways in which its lessons may be applied.

"Vocational guidance is not, and never can be, the literal interpretation of the square peg and round hole metaphor: it is not so inhuman. . . . Studies such as these are necessary to lay the foundations of a more objective system of vocational advising, but they do not indicate a mechanistic conception of human life. . . . The value of the experiment lies, therefore, in the extent to which it makes clear the nature of the problem, and shows how a necessary piece of social work which has been begun on an empirical basis may be extended on a more secure scientific foundation by the introduction of psychological methods."

[1] *Methods of Choosing a Career.* By F. M. Earle, M.Ed., B.Sc. Edited with a preface by Charles S. Myers, M.D., F.R.S. With a foreword by the Right Hon. the Viscount D'Abernon, G.C.B., G.C.M.G. London: G. G. Harrap and Co., Ltd. 1931. (Pp. 334; illustrated. 12s. 6d. net.)

EARLY THEORIES OF SEXUAL GENERATION

In the title of Professor Cole's volume on the *Early Theories of Sexual Generation*[1] there is nothing to indicate that the book differs from the semi-popular works on biological subjects which are issued in considerable numbers at the present day, and which doubtless have their use in disseminating an interest in scientific problems. Professor Cole's book is in a different category. It is a solid piece of historical research, carried out with scrupulous attention to accuracy and completeness, and it will, without doubt, occupy the position of a standard work of reference for those who take more than a superficial interest in the subject. Professor Cole refers to the common mistake of confining a historical narrative, whatever phase of science may be under discussion, to its more salient and striking features; such a method leads to erroneous conceptions, and these can only be avoided by a complete examination of all the facts. Theories of sexual generation lend themselves, more than is the case with most subjects, to the undesirable practice of culling the interesting details and ignoring their more prosaic but indispensable setting. This mistake will not be made here; it need only be said that the reader will find in the author's chapters on the history of the spermatozoa, the Preformation Doctrine, epigenesis, and the theories of fertilization and development, matter of absorbing interest, handled with genuine historical instinct. One may be allowed, by way of an aside, to make a reflection suggested by some of the old theories advanced on the subject of sexual generation. The following are among those which have been held by men of scientific standing: Generation is dependent on putrefaction of the ovary, or of the semen; spermatozoa are miniature human beings; the ovum contains a miniature human being; spermatozoa are animal parasites belonging to the genus Cercaria (Cuvier); the sexual elements in Adam and Eve contained, in ever diminishing miniature, every individual of the entire human race. Malebranche (1674) the philosopher truly remarks in reference to the last-named theory, that "the vision of the soul is indeed more comprehensive than that of the body." As a less philosophical comment, it may be suggested that it is wise to take the theories of scientists *cum grano salis*.

NOTES ON BOOKS

The second volume of *Recent Advances in Analytical Chemistry*[9] is devoted, according to title, to inorganic chemistry. It also includes a section on micro-analysis, and on the analytical examination of water and sewage. The presentation is generally in the form of abstracts of published papers, and some compression of detail has thus been unavoidable. More precise detail is furnished in the chapters dealing with the rare elements. In the chapter on water and sewage an account is given of the oecology of the living organisms developed in various forms and degrees of pollution. This is a subject usually much neglected, but one of great importance. The book is very comprehensive in reference to new methods; it includes a complete bibliography and an adequate index.

The recently published Proceedings of the Second National Congress[10] organized by the Italian League for the Campaign against Cancer, and held at Bologna last January, contains papers on the etiology of tumours, cancer, and tuberculosis, constitution and cancer, oncogenic disequilibrium and histogenic chemotherapy, and diagnostic and curative centres in Italy for malignant growths, as well as short communications dealing with the experimental, clinical, pathological, and statistical aspects of the question.

The first part of Messrs. Merck's *Annual Report*[11] for 1931 does not record any new drugs of outstanding importance, but contains notes on various subjects that are of general interest. Acetylcholine and other choline derivatives are finding increasing use on the Continent. A number of authors have reported favourably on the action of acetylcholine in various forms of arterial spasm, and Dejean found that it relieved migraine. Ephedrine appears to be finding an increasing use; about thirty references are given to papers on this subject. In addition to its well-established action in the allergic diseases, ephedrine has been found useful in preventing or in combating circulatory collapse, and in particular that due to lumbar anaesthesia. It has also been used to replace adrenaline in local anaesthesia, and is stated to produce no side actions. Finally, it has been used successfully in biliary and renal colic. The reports on the use of ergotamine include a number which mention the danger of the production of ergot gangrene. Antoine, however, suggests that the gangrene which sometimes occurs in puerperal septicaemia is due, not to ergotamine, but to gangrene-producing amines which originate in the febrile puerperium.

PREPARATIONS AND APPLIANCES

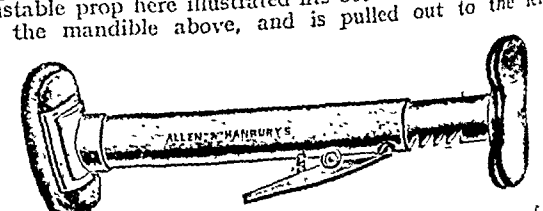
An Ether Inhaler and Jaw Support

Dr. G. A. Metcalfe (Bedford) writes: The apparatus here described is designed to give an efficient ether anaesthetic in cases where it is essential to keep the apparatus out of the surgeon's way. It is simple in construction, easily sterilized, portable, needs no special skill to use, and gives a full view of the face. It consists of an airway (A) connected through a wide-bore rubber tube (B) with the inhaler (C). The patient breathes in and out through the whole apparatus with perfect freedom. The tube is long enough to allow the inhaler to be placed in any desired and unobtrusive position.

The Airway.—The usual Phillips rubber type is used with a modification of the metal mouthpiece. This, made in two sizes, consists of an angled tube, the oval limb (*m*) of which takes the rubber airway. The round limb (*n*) projects at right angles to the mouth, and is designed to take the pipe (*p*) of the tube (B). It is short enough to fit below a Schimmelbusch facepiece, and can be used as an ordinary airway. To prevent breathing otherwise than through the airway an obturator (*o*) of rubber is slipped on to the oval limb, and fits between the teeth and lips. A spring nose-clip is used for the nose.

The Tube comprises about two feet of half-inch internal bore stout rubber tubing. Its upper end is connected with a curved metal pipe (*p*), which fits into the round limb of airway, and can be rotated in any direction desired. This allows of free choice of position of inhaler without danger of kinking the tube.

The Inhaler consists of a metal pot (*a*) weighted at its base, into which slips a cylinder (*b*). Near the base of (*a*) a wide-mouthed pipe (*y*) opens, which leads to the tube (B), and acts as the respiratory vent. A second small pipe (*d*), entering at the opposite side, acts as an intake for oxygen or ether vapour. The cylinder (*b*) is open at the lower end, and carries with it into (*a*) one or two layers of lint (*l*); these stretch across its mouth, and form a diaphragm upon which the anaesthetic drops. The friction of the lint holds the cylinder at any desired height, and the total volume of the inhaler can be altered by varying the position of the cylinder. Across the upper end is a strut, with a hole in the centre, which acts as a bracket for the drip funnel (*f*). The end is covered with a layer of lint, held in position by a spring clip (*h*), and pierced by the funnel. The inhaler consists, therefore, of two chambers, into the inside of which the anaesthetic is dripped, and through which the patient breathes.



Method of Use

Induce in the ordinary way; when the anaesthesia is deep enough, pass the airway, and adjust the obturator and nose-clip. Continue with the ordinary mask for a few moments longer. Fit the curved pipe (*p*) to the airway, turned in the desired direction. Let the ether drip through the funnel with tap open. Later, turn the tap on the funnel to allow a steady feed, and fill the funnel as required; fit the intake pipe to an oxygen or ether vapour supply if desired. For large patients a piece of gamgee may be clipped over the cylinder, but if breathing is agitated it is advisable to remove the top covering altogether, and push the cylinder in. For children one layer of lint on the diaphragm is all that is necessary.

Only a small quantity of anaesthetic is required. The jaw must be kept well forward to close the mouth and ensure a free airway, and a jaw prop, such as Cave's, or that here described, is a very useful adjunct in many cases. Perfect aeration is obtained, and anaesthesia is smooth and economical. The apparatus can with advantage be used for all other anaesthetics.

A Jaw Prop

With an artificial airway in position it is often necessary and sufficient to hold the chin up in order to obtain a free air passage while administering an anaesthetic. The simple adjustable prop here illustrated fits between the clavicle below and the mandible above, and is pulled out to the length desired, where it automatically fixes itself by means of its ratchet. The ends are grooved and padded to fit the [illegible] and the upper end is made to rotate so that it can [illegible] into line with any part of the ramus. It is sometimes necessary to hold the prop in position by means of tape [illegible] round the neck.

The ether inhaler and jaw prop have been made for us by Messrs. Allen and Hanburys, Ltd., 48, Wigmore Street, London, W.1.

THE CLINICIAN'S PRIDE OF PLACE

The annual Harveian Oration at the Royal College of Physicians naturally and properly offers each year a tribute of eulogy and appreciation to the memory of a great name, and repeats the time-honoured exhortation to the Fellows of the College to seek out the secrets of nature and to cultivate the excellent virtues of mutual affection and charity. The discharge of these pious responsibilities once accomplished, the Orator of the occasion is left with a large measure of liberty, and his task is to use this liberty to some selected end not altogether remote from the official text committed to his charge. It is therefore quite within the fitness of things that in the Oration of 1931 Dr. Robert Hutchison has felt himself free to review some of the features of medical life and work in the modern generation, to sharpen his comments on these by a reference to the virtues of a former age, and to inquire how at the present day the search for truth in the field of medicine may be most effectively promoted.

Not all that Dr. Hutchison observes is pleasing to him. In some not unimportant respects the present generation, he considers, has declined from the standards of its fathers; much modern work is impressive by its volume rather than by its weight; and haste and exhibition are cultivated at the expense of intelligent interpretation and sound judgement. Further, and this may perhaps be regarded as the most unkind of his comments, he adds the accusation of a lack of humour, and we may gratefully acknowledge that, certainly in this respect, he himself endeavours in genial fashion to atone for our deficiencies and to encourage us by his example. Perhaps not quite seriously he suggests that the writing and publication of scientific articles and papers should be suspended for the period of five years, in order that time may be secured for the culture of the imagination and for the emergence of ideas. Haste to secure priority of publication, he argues, is little likely to be associated with fruitful contemplation or deliberate thought, and he may claim in his support both the modern assertion of the value of mental quiescence and the ancient experience of the Psalmist, "while I was musing the fire kindled." For this indictment few will deny some measure of justification. Surely, however, there is another side to the shield. If it is true that a state of "moral and intellectual chaos" is a note of the present age, not less true is it that there exists to-day a very firm conviction that there are many things yet to be known, and a very resolute and practical determination to know them. Moreover, it may be doubted whether the advent of the genius for whom Dr. Hutchison longs, and who is to bring order out of the confusions which oppress us, will be hindered or delayed either by the further accumulation of facts or by the vagaries of those whose discretion is not that of the angels.

In the discussion of two of the issues proposed by Dr. Hutchison little if any help can be obtained from the record of the past. Happily or unhappily, it is on modern experience and judgement that we must decide both the relation of laboratory tests to clinical work and the degree to which specialization may advantageously be cultivated. Not for the first time Dr. Hutchison stands firmly for the necessity and value of the clinician, whose "pride of place" he recognizes has had to suffer some measure of challenge from the laboratory expert and the specialist, and whose methods do not pretend to the dramatic quality of those of the experimental physiologist. Indeed, the Harveian injunction to seek out the secrets of nature "by way of experiment" cannot, except in a very limited sense, be applied at the bedside, for here it is the welfare of the individual patient rather than the establishment or demonstration of general propositions that commands the field. Such an admission, however, is not to allow that the clinician stands outside the scientific boundary, or that no extension of knowledge, or new discovery, or illuminating generalization, is to be expected at his hands. Dr. Hutchison produces ample reasons to deny this suggestion, and in our own time the work of the late Sir James Mackenzie, to quote no others, is surely a convincing illustration of the value of observation on facts as nature presents them, and apart from the limiting influences of artificial and experimental conditions. In clinical work the problem is the individual man—anatomical, physiological, and psychological—and it is the clinician alone who is in a position to survey the whole of the field, and thus to obtain a sound basis for judgement.

If, as is suggested, the clinician has in recent days suffered in "his pride of place" the question may be asked whether in some measure he has not himself to blame. Has he not too readily yielded to others methods of observation which he might quite reasonably have cultivated himself? Is it really essential that all specimens of clinical material, which, as a matter of routine, are now largely passed into the laboratory, should receive a particular judgement, or that relatively modern aids to observation—such as the micro-cope, the ophthalmoscope, the laryngoscope, and the sigmoidoscope—can be profitably used only by a limited group of experts? That in such studies there may be occasions when the most experienced judgement available is required, all will allow, but this does not exclude the value of a less extensive proficiency and the more a routine practice is cultivated the higher rises the proficiency level. The clinician claims that his method is that of "observation." Opportunities for "observation" have enlarged and multiplied. Has the clinician always proved himself equal to these new occasions? Certainly the more he acts as the mere collector of the observations of others, rather than as a first-hand observer on his own account, the more his

"pride of place" is likely to suffer eclipse. If he claims to survey the whole field, let him survey it so far as possible with his own eyes, and not with the eyes of others; the ideal may not be completely attained, but as a ruling motive it will contribute to a constantly improving standard of achievement.

Dr. Hutchison regrets the growth of specialism, though he allows that it cannot be avoided; his objection is that, while favouring the accumulation of facts, specialism is bad for the philosophy of knowledge and prejudicial to a healthy use of the imagination. It is, of course, useless to regret the inevitable, and no one will deny that the cultivation of special branches of medical study and work has meant not only an increased knowledge of facts, but also an increased ability to relieve human suffering, and if the imaginative faculty has suffered in the process, the loss is not without its compensations. In the practice of specialism as a form of medical activity the manifest danger is the tendency to forget that the patient is one and indivisible, and that no true estimate of his needs can be based, either scientifically or safely, on an examination which, however brilliant or modern may be its fashion, is admittedly limited and incomplete in its survey. In other words, whatever the experts in some specialized departments may say about organs or functions, the care of the patient—and this is the supreme claim—must rest on some broader and more comprehensive outlook. In a growing recognition of this truth, and in a consequent appreciation of the value of accurate and comprehensive observation as a basis for knowledge and judgement, Dr. Hutchison detects an increasing tendency to recognize that the physician is essentially a student of nature, and that he must take Nature as he finds her. Experiments and laboratories and specialists have indeed much service to render, but neither in the interests of individual patients nor in the movement towards fullness of truth can the traditional and established habit of clinical observation be allowed to decline from its pride of place.

TOXIC GOITRE

That the thyroid gland in health exerts a considerable influence on the rest of the body is well known. This function is variable, and subject to alteration in response to stimuli of a physical, chemical, or psychological nature. Much of the physiological action of the thyroid gland is still obscure, and it is rather from the pathological changes in the gland associated with certain clinical phenomena that the greater part of our knowledge of its activities has been derived. From the time of Reverdin and Kocher the profound effect on the whole body of the removal of the gland in man and animals has been established, together with the relief obtained by feeding or grafting thyroid tissue; and clinical observations have led to the separation of a series of forms of hypothyroidism or myxoedema of operative or spontaneous origin. The conditions accompanying the over-active phase of disturbances of the thyroid have also received much attention from both clinicians and pathologists. Until recently these states of hyperthyroidism have remained confused, owing to the variable classifications adopted, according as one or other of the many clinical and histological phenomena has been given prominence. Rienhoff, who has himself contributed a great deal to the elucidation of the pathology of the thyroid gland, points out[1] that this confusion was inevitable, until, first, a means became available by which the presence and degree of hyperthyroidism could be measured mechanically, thus eliminating the personal equation of the clinician; secondly, until a drug was found by which the active stage of the disease could be made less active; and thirdly, until controlled observations were made of the association between the gross and microscopical changes in the thyroid gland and the various phases of intensity of the disease and the fluctuations of the metabolism of the patient.

Estimation of the basal metabolism has now afforded the clinician a sound method by which to follow closely the increase and decrease in the metabolic rate; and by the use of iodine it is possible to control to a notable degree the active phase of the morbid process. As a result of the correlation of clinical data and histological changes, it can now be definitely laid down that hyperthyroidism is associated with an increase of the parenchyma of some part of the gland, together with a decrease in the amount of colloid. Hypertrophy of the epithelial cells is accompanied by hyperplasia, causing an infolding of the epithelium lining the follicles. With the remission produced by administering iodine, a striking change takes place in the microscopical structure of the gland. The infolding of the epithelium is smoothed out, the epithelial cells are shrunken and flattened, the follicles become more spherical and regular in size, and are distended with colloid. In contradistinction to the hypertrophy and hyperplasia observed in the active phase of the disease, this change has been termed "involution," accompanying as it does the inactive phase of remission of the disease process, and tending to bring back the gland to a more normal appearance. In some regions of the gland the process of involution goes further, and produces large, colloid-containing cysts or groups of dilated colloid-containing acini indistinguishable from colloid adenomata. These areas of hyper-involution may be seen in naked-eye sections of the gland, and even palpated as nodules on its surface. We have thus obtained guidance in interpreting the macroscopic and histological appearances of the thyroid gland in Graves's disease, which is characterized by spontaneous exacerbations and remissions. The increased activity is accompanied by increase of the areas of hypertrophy and hyperplasia, the remissions by involution with reversion to colloid formation, and often hyper-involution with cystic degeneration, so that an actual negative phase may take place in parts, such as occurs in the goitre of hypothyroidism. Increase of interstitial fibrous tissue may be found—the scars of former disease. Thus, in

[1] Rienhoff, W. F., jun.: *Medicine*, 1931, x, 257.

ALAWAI & ... BROOKMAN'S PARK STATION (L.N.E.R. main line). ... Tavistock Square, W.C.1

gland from a patient with long-standing disease, the ppearances may be complicated and bizarre, but we ow have a clue to help us in elucidating them

The permutations of hyper- and hypo-thyroidism are sponsible for the diverse symptoms of dysthyroidism t is the nodular element which probably has caused ost confusion In more than half of 109 cases of odular goitre with long standing hyperthyroidism udied by Rienhoff and Lewis the morbid process was rictly limited to certain specific regions of the gland, ne tumours representing the product of the processes of ypertrophy and hyperplasia, and of involution In nother large group the nodular element was composed f regions of hyper involution In only 8 per cent were ue benign neoplasms or true adenomata found incidentally in a thyroid diffusely involved in the hyperophy and hyperplasia, so that the nodules in 92 per nt of the cases were not neoplasms in any sense, nd therefore cannot be termed "adenomata" Terms ich as "toxic adenoma" and "hyperfunctioning denomatous goitre" are misleading and incorrect if *pplied to the whole range of nodular goitre* Rienhoff refers that the clinical diagnosis should be nodular oitre with or without hyperthyroidism, as the signs nd symptoms suggest, or, in case the enlargement is mooth and diffuse, diffuse goitre—with or without yperthyroidism In accord with Dunhill,[1] Professor rancis Fraser, who opened the discussion on this bject at the Annual Meeting of the British Medical ssociation at Eastbourne, used the term "toxic oitre" to cover all cases of hyperthyroidism formerly alled exophthalmic goitre and toxic adenoma His aper is published at page 739 of our present issue

Ideas on the effect of iodine in the treatment of hyroid disease have lately undergone considerable odification When reintroduced by Plummer in 922, iodine therapy was shown to have a most striking ffect in rapidly preparing the patient for operative reatment, lessening the severity of the disease, and himinishing the operative risk The present position eems to be that at any phase of the disease iodine will educe the intensity of the thyrotoxicosis, but the isease seems to continue, even though in a modified orm Iodine does not reach the cause, therefore, lthough profoundly altering its effects It is Professor raser's practice to give iodine continuously, and by ombining it with rest in bed to bring the patient to minimum of thyroid intoxication and an optimum ondition for operative treatment The time taken to each this state may be much longer than ten days When operative treatment is not necessary, iodine is one of the most valuable methods of treatment available Treatment by x rays will often control the morbid rocess, especially in younger persons whose thyroid glands show no evidence of former disease It is to he surgeon, however, that we must look for help in lealing with the established disease Professor Fraser holds that surgical treatment is indicated in patients with nodular goitres, in those who do not improve rapidly, or continue to relapse and become chronically ill in spite of satisfactory management, or in those who, for financial or other reasons, cannot be submitted to adequate observation and treatment All along there have been advocates of surgery, but unfortunately the results of surgery are not uniformly good Much progress, however, has been made, and by special care of the patient before, during, and after the operation, by improved methods of anaesthesia, and by delicate handling of the site of operation, increasingly satisfactory results are being obtained

Yet something more is needed than successful removal of a large portion of the gland Many of the problems of thyrotoxicosis are still unsolved Their causation is almost unknown Infections—coccal, even tuberculous and syphilitic—may play a part, mental worry psychic trauma, endocrine and sexual disturbances may also be contributory factors Is the thyroid more commonly diseased than the other endocrine glands, or is it that the signs of its disturbance are more easily recognized The thyroid secretion affects the fundamental rate at which the cells of the body live There may be a different constitution of the cells of some, making them more susceptible Professor Fraser adduces evidence of a hereditary tendency In the established case the aspect of chronic scare is obvious to the layman in the bus It is the early cases that are difficult to diagnose *In health there must be a variable secretion to meet the* calls of everyday life, the variations may probably be considerable, and still within normal limits It is to be hoped that increasing knowledge will bring about earlier recognition of departures from the normal and that they may be sooner treated, with relief by medical means partial control by radiology, or with restoration to health by timely and skilful surgery

THE TRAFFIC IN NARCOTIC DRUGS

The annual report of the British Government to the League of Nations for the year *1930* on opium and other dangerous drugs is reassuring as regards the control of the traffic in narcotics in this country, but the seizures made in the United States, in Egypt, and in certain British Colonies and India show that there is little or no reduction in the illicit traffic generally The conclusion derived from the evidence available is that if only all the Governments, by legislation and administration, gave effect to the obligations involved in the Opium Conventions of 1912 and 1925, the contraband trade could be brought under control if not entirely extinguished The Dangerous Drugs Acts 1920 to 1925, have loyally carried into effect the treaty engagements of the British Government and might serve as models for other Governments to follow It is claimed in the report that "drug addiction is not prevalent in Great Britain" Raw opium and coca leaves are, of course, not produced here and the only ports for their importation are London Liverpool and Southampton Only two British firms both in Edinburgh are licensed to manufacture morphine and 49,637 ounces of morphine and its salts were manufactured during the year 1930 The same two firms

were the only ones licensed to make heroin, and 4,197 ounces of that alkaloid and its salts were produced during the year. One firm only, situated in Battersea, is licensed for the manufacture of cocaine, and 12,490 ounces of that alkaloid and its salts were the amount of the year's output. There were no seizures of illicit drugs of any importance in Great Britain. On the other hand, 100 kilograms of heroin were seized at Rotterdam in the course of transit between Constantinople and Hamburg, being part of a wholesale contraband trade financed by a wealthy gang of Japanese drug traffickers. Information was obtained that requests had been received by London firms for an illicit shipment of 1,400 kilograms of heroin to Shanghai. In 1930 63,634 lb. of raw opium were imported into Great Britain, more than half being Turkish, and about one-third of Indian origin ; 3,673 ounces of cocaine were imported, mostly from Germany and Holland ; 4,653 lb. of raw opium were exported, mostly to the United States. Last year 21,593 ounces of morphine were exported from Great Britain, or little more than half the amount exported in the previous year, and there was a similar reduction in the legitimate exports of heroin. On the other hand, the exports of cocaine in all its forms showed an increase from 3,920 ounces in 1929 to 5,510 ounces in 1930. Reference is made in the report to the London Conference in 1930 of representatives of countries manufacturing narcotic drugs which sought to determine quotas of the world's legitimate requirements to be apportioned to each. That method of limitation has, however, been rejected by the more recent conference held at Geneva, at which fifty-seven States were represented. This conference has drafted a new convention to supplement the provisions of the Hague Opium Convention of 1912, and that of Geneva of 1925, in order to give effect to Article IX of the earlier convention and secure "the limitation of the manufacture of narcotic drugs to the world's legitimate requirements for medical and scientific purposes."

STANDARDIZATION OF VITAMIN D

A short monograph on the quantitative estimation of vitamin D by radiography has been prepared by a group of workers at the National Institute for Medical Research.[1] The authors have shown that the curative effects of vitamin D on the epiphyses of rachitic rats can be divided into a scale containing twelve recognizable stages. There is an approximately linear relation between the effect produced and the logarithm of the dose of vitamin, and doubling the dose causes a rise of approximately two stages in the scale of healing. The dose required to produce full healing (Stage 12) is therefore about forty times as great as the dose that produces the smallest recognizable effect (Stage 1). The standardization of vitamins has long been notorious for its difficulty. The slightest variation in technique produces wide differences in the results obtained, and individual variation remains as a possible source of error even when all errors in technique have been eliminated. The fact that vitamin D produces a graded action over such a remarkably wide range of dosage is an additional difficulty attending its estimation. The authors in their report have considered in detail all the chief sources of error. The basis of their method consists in comparing the action upon pairs of rats of the substance to be tested and that of a standard preparation of irradiated ergosterol. They claim that with twenty pairs of rats a value with a probable error of 8 per cent. can be obtained. This is a remarkably high standard of accuracy for vitamin estimations. Biological assay is a very young science. It is specially distinguished for the unexpected number of difficulties and sources of error with which workers are beset, and the report under consideration illustrates this point very clearly. It is, however, certain that no serious advance can be made in the study of any substance unless some method can be devised for its accurate measurement. Hence the authors of this report are to be congratulated on having accomplished a very laborious but useful task.

FOOD PROBLEMS

The economic importance of maintaining New Zealand lamb in a sound condition during its transport to this country may be gathered from the estimate that a saving of 1 per cent. in the total loss of weight in an annual season's export would result in the gain to the industry of nearly £100,000. The problems relating to frozen meat have recently been studied by the Food Investigation Board under the Department of Scientific and Industrial Research, and some two years ago, as narrated in the Board's report for 1930,[1] an expedition went to New Zealand, under the leadership of Dr. Ezer Griffiths, to make a comprehensive scientific survey of the trade in frozen mutton and lamb, including the factors influencing bloom and quality. It appears that a considerable percentage of New Zealand lamb carcasses are originally defective in bloom owing to such ante-mortem causes as breed, age, nutrition, and lack of rest before slaughter. After slaughter the carcasses are hung for varying periods on a cooling floor, where their temperature falls to near that of the surrounding atmosphere. They are next frozen in refrigerating chambers, and when they have fallen to chamber temperature are stacked in refrigerating stores for periods ranging from one week to four months, until the time for shipment. Transport from the store to the ship is effected in insulated railway wagons or lighters. The ships usually discharge in London, where the meat, after further cold storage ashore and subsequent conveyance by insulated vehicles, reaches Smithfield market. At the original refrigerating stores in New Zealand batches of lambs of similar history were selected and used in subsequent stages as material to illustrate the effects of various conditions on the quality and bloom of the meat. It emerged that loss of weight not only partly determines the degree of loss of bloom, but also, as noted above, that it is an important monetary consideration. At the present time 80 per cent. of the beef imported into Great Britain comes in the chilled state from South America. When shipped from ports on the River Plate it reaches this country in twenty to twenty-eight days. If a trade was established to import chilled beef from Australia to Great Britain, the beef would have to be maintained in the chilled state for voyages of about forty days. To test this point experimen-

[1] Report of the Food Investigation Board for the Year 1930. London: H.M. Stationery Office. 1931. (3s. net.)

ALAWAI & [illegible]
BROOKMAN'S PARK STATION (L.N.E.R. main line). [illegible] Tavistock Square, W.C.1.

were carried out for the Board with beef at 0° C. and air humidity of 79 per cent. In still air after forty-two days the meat was found to be sour and penetrated by moulds. In fanned air, under conditions otherwise similar, the beef was perfectly sweet after sixty days, and the growth of moulds was insignificant. The precise optimum conditions of humidity and air flow have still to be determined, but a period of sixty days would more than suffice for Australian chilled beef to be safely landed in this country, and the further investigation of the problem may open the way to a new industry. Among many other topics dealt with in the report are the freezing of living tissues, acetaldehyde in plant metabolism, the scientific basis of curing, evaporation from eggs, the corrosion of tin and iron, the liver fat of fish, the detection of the dew point, and disease in stored apples.

SCIENCE AND THE PUBLIC

A paper read at the annual meeting of the American Medical Association by Dr. A. C. Ivy of Chicago[1] discusses an important matter to which the attention of the medical profession and others in this country might well be more effectively directed. The address is entitled "A deficiency in present-day education," but its point is not thereby distinctly indicated. It may be stated thus. Admitting that, in the common phrase, this is the age of science, and that the achievements of physical and biological and medical science are generally recognized, how is it that the teachings and methods of science are not universally accepted and acted upon, and that so large a number of presumably well-educated people still fall victims to the most manifest superstition and fraud, and even develop an enthusiasm for anti-medical and anti-scientific crusades of various kinds? "Does society think scientifically? . . . or does science have to persuade, 'sell' or even propagandize society to receive its discoveries and truths? . . . The dawn of scientific understanding in society is still awaited . . . there exists among the most enlightened peoples an emotional hostility to biologic and medical science."

One of the chief problems of the medical profession is "to bring about a better understanding of scientific medicine in society, to let society know that truth is the motive of medical science, and that facts, not beliefs, determine truth." The analogous, indeed the same, position in the ecclesiastical sphere, has manifested itself in no uncertain fashion, and there, too, it is evident that a surviving anti-scientific atmosphere still prevails, and that the task of the scientific thinker is not easy. Dr. Ivy asks, "Is present-day formal education coping effectually with this problem?" He concludes that there must be some deficiency in present-day education. Perhaps this is true in this country, as it is said to be in America. Science is more than ever before taught in our secondary schools, and, in some sort, in a large number of our elementary schools. In too many institutions, however, the teaching is confined to physics and chemistry, and even these are taught with stress upon their mathematical aspects and the multiplication of practical and meticulous details. The examining bodies who conduct general school and matriculation examinations are largely to blame for this. Two immediate reforms which should be made are the introduction of biology, leading up to and including human physiology and hygiene; and the stressing of scientific thinking and scientific method throughout, rather than the acquirement of a knowledge of more or less advanced detail. Members of the medical profession are largely educators themselves, and collectively they have much influence with those who control or guide education—both teachers and administrators. They certainly might do more than they have done to bring about such reforms as these.

FOUNDERS OF VITAL STATISTICS

In our time official statisticians are so active, and so many mathematicians have devoted their attention to statistics, that the subject of population is, to the uninitiated, suggestive of dreadful tables of figures and still more dreadful algebra. One may think regretfully of the days when people were less learned and wonder whether they were more entertaining—an impious thought, no doubt, but a natural one. Dr. Bonar's charming volume[1] will bring comfort to those who are interested in the history of ideas but care little for the technicalities of statistical methodology. He introduces us first to Giovanni Botero, who anticipated a leading idea of Malthus by more than two centuries, then takes up the less adequate conceptions of Raleigh and Bacon and the theories of Hobbes and Harrington. None of these writers were or could be statisticians in our sense of the word, but two of Harrington's contemporaries, John Graunt and William Petty, laid the foundations of a new order. Dr. Bonar puts these two remarkable men side by side in an interesting way; some of us would rate John Graunt a little higher and William Petty a little lower than he does. To speak of Graunt as "a city magnate," perhaps conveys a slightly exaggerated impression of his commercial status, while to say that Graunt "was rather discoverer than inventor," but that Petty was "a born inventor," while true in the sense in which Dr. Bonar is using the words, may seem to disparage the scientific originality of Graunt's work. Perhaps, also, the antithesis of Graunt as "the city magnate" and Halley "the distinguished astronomer" is too pointed. Of the three English founders of vital statistics, Graunt, Petty, and Halley, we should rank Graunt first in originality and scientific insight. Halley, who was a better-trained mathematician, and had access to better data, than Graunt, no doubt reached more accurate conclusions, while Petty's practical range was much wider. But Petty was not a scientific man at all in the sense that Graunt was. Dr. Bonar's account of Süssmilch is delightful; much the best we have seen. The old Prussian army chaplain was an attractive figure—"a man of kindly, lovable nature as well as of a solid good sense that seldom failed him and a genuine anxiety to reach the truth. His opinions on theology and politics were not allowed to bias his statistics; but perhaps because so frankly revealed, they have obscured the real value of his services by creating the impression that bias was probable." Hume, Price, and Arthur Young are, for various, non-statistical, reasons names more familiar to English readers than Süssmilch, but upon each Dr. Bonar has much, both interesting and

[1] *Theories of Population from Raleigh to Arthur Young.* By James Bonar, M.A., LL.D., F.B.A. London: G. Allen and Unwin, Ltd. 1931. (Pp. 253. 10s. 6d. net.)

instructive, to say. Poor Richard Price is no doubt better remembered as a target for Burke's rhetoric than for any other reason, but is it quite correct to say that "we are largely indebted to him for Burke's political philosophy"? Many would maintain that Burke's finest political thinking was done before the French Revolution took hold of his imagination.

METHODS OF MEDICAL EDUCATION

The nineteenth series of the valuable *Methods and Problems of Medical Education*,[1] which are distributed to teachers and administrators in medical schools and hospitals, is entirely devoted to teaching and research in medicine in the division of biological sciences in the University of Chicago. The inclusion of medical education as a whole in the division of biological sciences has come about in the following way. In 1901 the trustees of Rush Medical College transferred to the university the pre-clinical subjects, including pharmacology, pathology, and hygiene. In 1916 Mr. Abraham Flexner of the General Education Board was invited to make recommendations for a complete medical school, and as a result all the branches of medicine, except psychiatry, are now located in the quadrangles of the university, and the clinical departments are organized almost exclusively on the basis of full-time appointments, the conviction as to the desirability of this plan having strengthened rather than diminished. The activities of the school are here described in twenty-five articles, accompanied by numerous plans and photographs of the departments. The intimate relation of medicine to biology as a whole is aimed at, and, while it is recognized that most of the students will become practitioners, arrangements for research and for the training of a continuous supply of investigators in the various branches of medicine are provided. The special foundations for medical research are described by the professors of pathology and biochemistry, Dr. H. G. Wells and Dr. A. B. Hastings, and their activity is shown by the record of four hundred papers from the Otho S. A. Sprague Memorial Institute, and about a hundred articles from the Douglas Smith Foundation, both of which are under the direction of Professor H. G. Wells. The history of neurological teaching is interesting: at first the professor of neurology devoted himself to fundamental questions relating to the structure and function of the nervous system, without any immediate reference to clinical applications; in 1907 the department of neurology was merged in that of anatomy, and all medical students are taught the rudiments of neuro-anatomy, and those who so desire are encouraged to undertake neurological research. In 1927 an additional division of neurology, now under the direction of Professor Percival Bailey, was established; there are two assistant professors of neurology attached to the department of medicine: but the neurological work is carried out in seven rooms in the surgical clinic, one of which is a large histo-pathological laboratory. Professor Bailey while believing that it is neither necessary nor desirable that every neurologist should operate upon his patients points out that the history of neuro-surgery clearly shows that whoever operates upon the nervous system should be a trained neurologist. As long ago as 1897 Bechterew of St. Petersburg described neurology as in a transitional period akin to that experienced by ophthalmology, gynaecology, and oto-laryngology. Among the other articles, attention may be drawn to that on medical social service by Professor Ruth Emerson, who tells the reader the kinds of cases, such as those of hyperthyroidism, cardiac disease, and tuberculosis, which are specially followed up into their homes. In an article on the degrees conferred, Dr. B. C. H. Harvey says that the thesis for the M.D. is regarded as indispensable on account of the critical ability, sound judgement, and training fostered by the labour thus spent.

[1] *Methods and Problems of Medical Education.* Nineteenth series. New York: The Rockefeller Foundation. 1931. (Pp. 220; illustrated.)

The Mitchell Banks Lecture will be delivered by Sir Robert Jones, Bt., in the theatre of the Medical School at Liverpool University on Thursday, November 19th, at 4 p.m. The title is "The problem of the stiff joint."

We regret to announce the death, at the age of 79, of Sir Edward Marriott Cooke, K.B.E., M.B., late Commissioner of the Board of Control, and formerly superintendent of the Worcester County Asylum, Powick.

MEDICAL CANDIDATES AT THE GENERAL ELECTION

The following members of the medical profession have been nominated as candidates for election to the House of Commons at the forthcoming General Election on Tuesday, October 27th.

ENGLAND

London Boroughs

Dr. C. R. Cooke-Taylor (L.N.), Camberwell (Dulwich).
Sir Henry Jackson (C.), Wandsworth Central.
Dr. W. J. O'Donovan (C.), Stepney (Mile End).
Dr. Esther Rickards (Lab.), Paddington North.
*Dr. A. Salter (Lab.), Bermondsey West.

English Boroughs

*Mr. Somerville Hastings (Lab.), Reading.
Dr. G. B. Hillman (C.), Wakefield.
Dr. A. B. Howitt (C.), Reading.
Dr. J. W. Leech (C.), Newcastle-upon-Tyne (West).
Dr. W. S. Russell Thomas (L.), Ilford.

English Counties

*Dr. Christopher Addison (Lab.), Wiltshire (Swindon).
Dr. F. G. Bushnell (Lab.), Somerset (Taunton).
*Dr. F. E. Fremantle (C.), Hertford (St. Albans).
Dr. L. Haden Guest (Lab.), Buckinghamshire (Wycombe)
*Dr. H. C. Haslam (C.), Lincolnshire (Horncastle).
Dr. R. A. Lyster (Lab.), Hampshire (Winchester).
Dr. G. V. Worthington (Lab. Nat.), Gloucester (Forest of Dean).

WALES

Welsh Counties

*Dr. J. H. Morris-Jones (L. Nat.), Denbigh (unopposed).
*Dr. J. H. Williams (Lab.), Carmarthen (Llanelly).

SCOTLAND

Scottish Burghs

*Dr. W. E. Elliot (C.), Glasgow (Kelvingrove).
*Dr. T. Drummond Shiels (Lab.), Edinburgh (East).

Scottish Counties

*Dr. R. Forgan (New Party), Renfrew (Western).
*Dr. Joseph Hunter (L.), Dumfries.

THE UNIVERSITIES

*Sir Ernest Graham-Little (Ind. Nat.), London University.
*Professor T. Sinclair (C.), Belfast (Queen's) University (unopposed).

* Denotes member of the late Parliament.

THE RELATION OF FOREIGN SUBSTANCES TO THE HUMAN BODY*

BY

G GORDON BRUCE, F R C S

SURGEON, ROYAL ABERDEEN HOSPITAL FOR SICK CHILDREN, ASSISTANT SURGEON, ABERDEEN ROYAL INFIRMARY

Man is constantly beset by dangers from cold and storm, by pathogenic organisms, and by the impaction of moving objects, and from the remotest times foreign bodies and hateful missiles have penetrated his tissues and lodged in his body. It has been affirmed that military surgery had its origin in the treatment of wounds inflicted by darts and arrows during the siege of Troy, and some of the earliest surgical instruments were designed for the extraction of arrow heads in the long Peloponnesian war over 400 years before the Christian era. But all foreign bodies are not of a harmful nature, in the Middle Ages they served as ornaments and charms to heal disease and to avert evil spirits, and at the present time they are deliberately inserted into the body in the course of many surgical operations.

On the Surface of the Body

Precious stones and gems set in gold have from time immemorial enhanced the charms of the most beautiful women of the age, and in the far distant past, 5,000 years before Christ, the pre-Dynastic women of Egypt wore necklaces of cornelian and agate, amulets in faience, and bracelets inlaid with lapis lazuli and fastened by flowers made of gold. In Peru the wearing of ornaments was not confined to the gentler sex. When the royal offspring had reached the season of manhood, the Inca, addressing them affectionately as "Children of the Sun," pierced their ears with a golden bodkin, which was allowed to remain until an opening had been made large enough for enormous pendants, which gave them, with the Spaniards, the name of Orejones. This ornament was so massy in the ears of the sovereign that the cartilage was distended nearly to the shoulder, producing what seemed a monstrous deformity in the eyes of Europeans, though, under the magical influence of fashion, it was regarded as a beauty by the natives. The Botocudos, a savage Brazilian tribe, practised similar customs, and inserted wooden plugs into the lower lip and lobes of the ear, causing great protrusion of the lip and a wide repulsive mouth.

In mediaeval times superstition vied with religious fanaticism throughout Europe and Asia; talismans and amulets were worn by the devout, and the relics of saints were more valuable than gold or precious stones. An enlightened age may scoff at the beliefs and superstitions of the Middle Ages, but the plague, or Black Death, which spread over Europe and wiped out a quarter of the population, may well have driven men's thoughts to charms and talismans which happily might avert the impending calamities of mankind. Nor did Great Britain escape from the superstitious practices of the times. "Pooh," said Raleigh, "I wear an amulet and have a spell of art magic at my tongue's end." In Scotland, necklaces of coral beads are thought to possess magic powers, and in the marriage ceremony the finger ring still holds as prominent a place as it did amongst the superstitious marriage rites of the ancient pagan world. Poisoned rings are said to have been the invention of the Italians, who inserted the poison in a receptacle where the jewel is usually set. Attached to the inner surface of the ring was a sharp point which, when the hand of the wearer was grasped, scratched the flesh and injected the poison. Rings were also used for carrying strong poisons secretly, such as arsenic and corrosive sublimate, and in this manner many were enabled to commit suicide after being imprisoned.

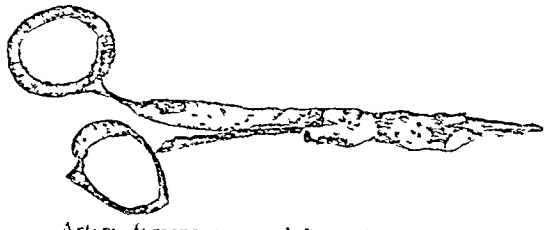
An animal's hide, substituted for human skin, is the most amazing of all foreign substances found on the surface of the body.

Macgowan[1] states that traders in the Chinese Empire kidnap a boy, skin him bit by bit, and transplant on the denuded surfaces the hide of a dog or bear. The subject must be rendered mute by destruction of the vocal cords, made to use all fours in walking, and must be submitted to such degradation as to blight all reason. The process is so severe that only one in five survive. A "Wild Boy" exhibited in Kwangsi, had the entire skin of a dog substituted and walked on all fours. It was found that he had been kidnapped, and his proprietor was decapitated on the spot.

The Papuans of Dutch South Guinea have a peculiar custom of fastening into the muscles of the right arm a certain portion of the flesh of a boar and of allowing it to remain there, to fester slowly, putrefy, and wither. They profess to gain strength from the animal in this manner.

In the Tissues

Small sterile bodies are soon encapsuled and become sufficiently inert to escape our notice and our memory. Needles may travel for a considerable distance from their point of entry. In 1802 Dr. Lettsom spoke of an old lady who sat on a needle, it passed from the injured leg to the other, from which it was extracted. Cases of tetanus have arisen from air-gun pellets and spicules of wood. Infected objects cause local suppuration and if near the surface, soon become extruded, but shrapnel or shell case, lying in the deeper tissues or impacted in bone, remain embedded in the depths, and may excite recurrent attacks of inflammation. During the great war, anaerobic organisms were carried into wounds by missiles bearing threads of khaki and particles of the actual soil of the battlefield. Many of us have not forgotten the pale, restless men, scarcely recovered from the initial shock and haemorrhage of their wounds, the emphysematous limbs, and the grey green muscles which discharged a thin, offensive, putrid pus characteristic of the most tragic of all infections.



What is the relation of foreign substances to malignant disease? Chimney sweep's cancer has been traced to particles of soot, repeated applications of tar have caused epitheliomata, cancer of the tongue has followed irritation from a denture, and the pressure of a pipe stem predisposes to tumours of the lip. Yet there are no grounds for supposing that metallic bodies which have lain for many years in the tissues play a part in the etiology of malignant disease. Tissue reactions undoubtedly occur. Foreign bodies excite a growth of fibrous tissue, Lane's plates have led to the formation of adventitious bursae, and cases of paraffinoma of the rectum have followed the treatment of prolapsed piles by paraffin injections.

Results in modern surgery depend on the asepticity of suture material which can be left with safety in the closure of wounds. In the past, buried ligatures were a common source of sepsis, and secondary haemorrhage from large vessels was not unusual, but with the dawn of the aseptic era septic ligatures have been forgotten, and foreign bodies are now freely used in surgery. The fractured ends of bones are fixed in apposition with plates, screws, and intramedullary bone pegs, skull defects are closed with sheets of metal, and innumerable silver clips control haemorrhage from small bleeding vessels in cerebral operations. Within recent years radium needles and radon seeds have been used in the treatment of certain types of malignant disease. But our methods are not yet fool proof, and a lurking fear still haunts a surgeon's mind that he unwittingly may leave a gauze strip drainage tube, or artery forceps in the peritoneal cavity. Such delay the healing of wounds and may cause intestinal obstruction. Lester Williams[2] reports a case of acute intestinal obstruction due to a drainage tube left in the abdomen twelve and a half years before.

In August 1912 an appendicular abscess was drained with a rubber tube the appendix was removed three weeks later and the patient made an excellent recovery. He was readmitted in January 1925 suffering from intestinal obstruction. A tubular structure was discovered passing from the right iliac fossa into the left side of the pelvis. This proved to be a piece of rubber tubing 15 cm. in length and 1 cm. in diameter. The distal part of the tube, together with three

* A paper read before the Aberdeen University Medical Society.

feet of the small intestine, had passed through an aperture in the root of the pelvic mesocolon The bowel was reduced and the opening in the mesocolon closed, the patient made a good recovery Moynihan[3] mentions an interesting case a woman underwent an operation for appendicitis Three years later the abdominal cicatrix gave way and thirty-four strips of gauze were extracted one by one The operator had not dressed the wound himself, but had ordered that one strip of gauze should be introduced daily This was done most conscientiously and, as he had omitted to direct the daily removal of the strip, thirty-four were introduced but never removed, the wound ultimately healed over them Metal instruments ulcerate into neighbouring organs In 1922 Dr Leach of Beauly presented to the surgical museum of Aberdeen University a pair of pressure forceps removed from the rectum of a woman thirteen years after a hysterectomy

Artery forceps removed from the rectum

had been performed for a myoma weighing 11 lb In the interval the woman had suffered attacks of partial intestinal obstruction The forceps lay embedded in the posterior wall of the rectum and on removal was found to be deeply eroded

Central Nervous System and Organs of Special Sense

Although a seemingly trivial wound has caused death, amazing degrees of trauma have been borne without a fatal issue

In the famous "American crow bar" case[4] a premature explosion drove a tamping iron, 43 inches long, 1¼ inches in diameter and 13½ lb in weight, completely through a man's head He did not lose consciousness, and walked up a flight of stairs to have his wound dressed His convalescence was uneventful but it is said he was no longer capable of performing the duties of a foreman An equally wonderful case is described by Dubrisay,[5] of a man aged 44, who forced a dagger 10 cm long and 1 cm wide into his brain He held the dagger with the left hand and with a mallet in his right, he drove the dagger inwards An attempt at extraction failed He was then placed on the ground, and held by two persons while traction was made with a carpenter's pliers The dagger refused to move He was then taken to a coppersmith's where he was fastened by rings to the ground, and strong pincers were placed over the dagger and attached to a chain which was attached to a cylinder revolved by steam force At the second turn of the cylinder the dagger came out During the extraction the patient remained perfectly cool and complained of no pain He soon returned to work

During the great war, lacerated scalp wounds, depressed fractures of the vault, and long-infected tracts containing fragments of bone, projectiles, and disintegrated brain substance, presented interesting problems in surgery. Although the accurate localization of foreign bodies gave a decided impetus to surgical attack and careful debridement of the scalp and cranial bones afforded a promising results, wounds with dural perforation showed a high immediate mortality from meningitis and encephalitis. This mortality was ultimately reduced by Cushing's method of "catheter suction," by means of which debris and small foreign bodies were removed and fragments of bone or shell case were discovered in the depths of the wound It is interesting to note that recovery has followed the extraction of foreign bodies from the ventricles

Although the eye is protected by the lids and by the projecting margins of the orbit, foreign bodies frequently enter the palpebral fissure or penetrate the globe of the eye Particles of steel or chips of stone become embedded in the cornea, and a beetle's wing, diaphanous and invisible to the naked eye, may excite a puzzling reaction. Peculiar accidents have followed a simple operation an ophthalmologist in Glasgow describes a case in which a piece of silver plating became detached from an iris forceps during a cataract operation and fell into the anterior chamber. The eye had to be removed. Very rarely a foreign body is retained in the vitreous or retina for a long period without loss of vision. Snell records a case in which a piece of steel was embedded close to the optic disc with retention of sight. It was visible by the ophthalmoscope eighteen months after the accident, and no diminution of sight was apparent The danger of sympathetic ophthalmia from an eye containing a foreign body is well known.

Small foreign bodies are frequently found in the nasal cavities of children. Hickman[7] gives an instance of a steel ring which for thirteen years had lain in the naso-pharyngeal fossa. Waring[8] mentions the case of a hotel maid who carried a rhinolith for twenty-five years, the nucleus was found to be a cherry stone. A pea, impacted in the nose, has been known to sprout

Children have the habit of inserting small objects into their ears. Winterbotham[9] reports an instance in which a cherry stone was removed from the meatus auditorius after lodgement of sixty years. Acute suppurative meningitis, and cerebral abscess have followed perforation of the tympanic membrane

A case is recorded in Schmidt's *Jahrbucher* of a boy who introduced a carob-nut kernel into his ear On the next day incompetent persons attempted to extract the kernel but caused only pain and haemorrhage In the afternoon the auditory canal was found red and excoriated, and deep in the meatus the nut was seen covered with blood In a few fever and delirium ensued, and chloroform had to be given before the nut could be extracted It was found that the agglutination of wax and blood had increased its size Unfortunately coma and signs of meningitis appeared, and four days after the operation the patient died

Cardio-vascular System

The heart may be penetrated by missiles from without or by needles migrating from the oesophagus It has been said that the contracted heart of a healthy man is as rigid as the biceps of an athlete, and that a foreign body which threatens to pierce the organ may be turned aside in its course. Death is not always instantaneous, but secondary haemorrhage, septic complications and embolism frequently lead to a fatal issue Curran[10] mentions the case of a soldier who, in 1809, was wounded by a bullet which entered the body to the left of the sternum between the second and third ribs There was little haemorrhage from the wound, and he survived fourteen days. The bullet was found in the pericardium A remarkable degree of tolerance is shown to metallic objects, bullets and needles have lain for twenty years encysted in the wall of the heart Foreign bodies, penetrating the chest wall, are drawn inwards by the action of the heart muscle.

Osler[11] reports the following case. A medical student while on the spree, thrust a pin into his heart The pericardium was opened and the head of the pin was found outside the right ventricle An attempt was made to extract the pin, but it passed into the heart and, it is said, caused the patient no further trouble

Leriche[12] relates the history of a boy who fell on the point of a needle His mother felt in the third interspace a minute elevation which moved with every beat of the heart Two hours later Leriche found that the needle had been driven inwards, and now lay in the thin wall of the auricle He extracted it and closed the cardiotomy wound with a single stitch The child recovered

With the advent of the great war, surgeons were given an unparalleled opportunity of studying the movements and course of foreign bodies which were capable of migrating from their point of entry. It became possible to compare the incessant whirling of a shrapnel ball in the right auricle with the slow swing, during systole and diastole, of a piece of metal in the left ventricle of the heart Small shot and rifle bullets traverse the arterial or venous systems Pellets, entering the left auricle, have found their way to the small peripheral arteries, and a rifle bullet, penetrating the left side of the heart has come to rest in the femoral artery, causing ischaemic gangrene of the limb Projectiles travel with or against the venous current. A shell fragment, displaced from the

ALAWAY & [illegible]
BROOKMAN'S PARK STATION (L N E R main line) [illegible] Tavistock Square, W C 1

phery, may reach the heart or enter the pulmonary
tut, and a piece of metal, seen oscillating in the right
cle, may be found a few minutes later in the right
vein. Foreign bodies causing menacing symptoms
uld be removed, and a deliberately planned operation
a fair chance of success.

orge von Manteuffel extracted a projectile from the
erior wall of the right ventricle in the case of a woman
21. After the pericardium had been opened, the entrance
nd of the bullet was seen upon the right ventricle 6 cm.
the apex. A blood stream, 50 cm. in height, spurted
each diastole. The orifice was closed by a silk suture
the bleeding stopped. The bullet was felt in the posterior
l of the right ventricle 1 cm. from the coronary artery.
heart was now lifted up by means of two fixation sutures,
the operator cut down upon the bullet, which he pressed
between the thumb and the left index finger. The second
nd, which bled but slightly owing to digital compression,
sutured, and the patient made a good recovery.

Respiratory System

The accidental inspiration of a foreign body has frently resulted in asphyxia and death. Crile has shown
t foreign bodies in the upper part of the larynx, by
tation of the terminal branches of the superior laryn-
l nerves, may give rise to serious and often fatal
lapse from reflex inhibitory action of the heart or
piration. A young man of 23, who was anaesthetized
order to extract a tooth, had a cork placed between
teeth to keep his mouth open. The tooth was extracted
slipped, together with the cork, into the pharynx. The
th was ejected in an effort at vomiting, but the cork
ered the larynx, and after violent struggles the patient
d from asphyxia in an hour. History relates that
ldren, while playing with toy balloons which they
late with their breath, have by inspiration reversed
em and have drawn the rubber of the balloon into the
ening of the glottis, causing death. Fatal results have
en averted by a violent fit of coughing, inversion of the
dy, or by tracheotomy. Foreign bodies may remain
many months in the larynx without the patient's
owledge.

Lennox Brown,[14] on examining a woman for suspected
ryngeal carcinoma or phthisis, found a tooth-plate impacted
the larynx. She had lost her false teeth during an attack
vomiting twenty-two months previously and, finding her
th missing, assumed that they had been thrown away with
e vomit.

Gould and Pyle[15] reported an ingenious criminal device
ic discovery on an Indian prisoner of a heavy leaden bullet,
inch in diameter, led to an inquiry, when it was ascertained
at the ball served in the formation of a recess at the base
the epiglottis. The ball is allowed to slide down to the
sired position and retained for half an hour at a time. This
eration is repeated many times daily until a pouch results
which criminals contrive to secrete jewels and money in
such a way as to defy the most careful search, and without
terfering with speech or respiration.

Coins, tacks, pins, beans, and collar studs may pass
rough the glottis and enter a bronchus. Young children
ffer most frequently on account of their habit of testing
ll things with their mouths. The act of coughing,
ughing, or crying may cause a small object to be drawn
nto the larynx. After an attack of choking, characterized
y cyanosis and aphonia, the irritation subsides; and a
pasmodic cough with muco-purulent sputum may suggest
ulmonary tuberculosis.

Lilienthal[16] reports the case of a boy of 6, who developed
ttacks of dyspnoea and cough immediately after tonsillec-
omy, when suction by means of a rubber tube had been
mployed. Numerous physicians had been consulted and
arious diagnoses made. Five months later an opaque body,
he size of a bean, was seen under the fluoroscopic screen
n the upper part of the chest. With each cough or expulsive
ffort the object flew upwards towards the neck, dropping
ack to its original position in the interval. A fragment
of rubber tubing, which must have been detached during the
revious operation, was extracted with the aid of the broncho-
scope.

An infected parenchymatous focus, surrounding a foreign
body in the lung, may give rise to pneumonia, abscess,
or gangrene.

Lapeyre[17] mentions an elderly gentleman who, while
smoking a cigarette, received a sudden slap on the back,
causing him to start and to take a deep inspiration. The
cigarette was drawn into the right bronchus, where it remained
for three months. Pneumonia supervened, and two months
later, during a violent fit of coughing, the cigarette was
expelled enveloped in a wavy, mucus-like mass.

Smallpeice[18] reports the case of a baby in which a flower-
spike of grass, 1½ inches long, passed through the upper air
passages and lung tissue, and was removed from a swelling
below the angle of the right scapula. A sinus led directly
into the right bronchus.

During the Boer and the Russo-Japanese wars, bullet
wounds of the lung seldom required surgical treatment;
but, with the advent of the great war, surgeons were
soon disillusioned by the high mortality caused by large
jagged projectiles, whose edges were plastered with debris
and pieces of clothing. If death did not take place in
the first two days from open sucking wounds, haemorrhage
and sepsis took a heavy toll at a later date. In the
extraction of foreign bodies from the lung, it is interesting
to contrast the open methods of Duval, Tuffier, and others
with the close method of Petit de la Villéon.

Alimentary System

"There is a providence which watches over innocence
and folly," and it is surprising how constantly foreign
bodies, if uniform in contour, pass through the oesophagus
and, after a brief rest in the stomach, travel through the
pylorus, the ileo-caecal valve, and are passed per rectum.
Hundreds of coins are swallowed by children, and operative intervention is seldom necessary. A lunatic in
England swallowed 10 oz. of screws and bits of crockery,
all of which were passed by the anus. One of Forille's
patients swallowed an entire set of dominoes. Fear of
robbery has often led to the swallowing of money or
jewellery. Vaillant, the celebrated doctor and antiquarian,
after a captivity of four months in Algiers, was pursued
by Tunis pirates and swallowed 15 medals of gold, on
arriving at Lyons he passed them all per rectum. But
fortune has not always smiled so kindly if we credit the
fate of the fourteen pages of Mahomet the Second, whose
bellies were ripped open in search of a stolen melon.
Foreign bodies with sharp edges may abrade or perforate
the oesophageal wall, causing a suppurative mediastinitis,
and many fatalities have followed the swallowing of
artificial dentures. Needles and fragments of bone,
migrating from the oesophagus, have penetrated the liver,
the heart, the aorta, and the portal vein. There are
many cases on record in which injury to the gullet or
stomach has taken place in the juggling process of knife-
or sword-swallowing. In 1502 Florian Mathias removed a
knife, 9 in. long, from the stomach of a man of 36,
followed by complete recovery. Bell performed gastrotomy
on a man who, while attempting a feat of legerdemain,
allowed a bar of lead, 10 in. long, 1½ in. wide, and 9½ oz.
in weight, to slip into his stomach. The bar was extracted
and the man recovered.

Hair balls of great size have been found in the stomach
of hysterical women who have been in the habit of eating
their own hair. Osler[19] describes a specimen in the
medical museum of McGill University, which formed an
exact mould of the stomach. The tumours are often
mistaken for cancer. Many have been diagnosed only on
the post-mortem table.

Powdered substances may cause death through violent
irritation of the stomach, and the ancient belief that gold
leaf and diamond dust were deadly poisons has its origin
in antiquity. The Chinese are supposed to have used
gold as a poison, especially for suicidal purposes, and at
the present day, when a high official puts an end to his
life, it is officially announced "he has taken gold
leaf." Madame de Montespan, one of the favourites of
Louis XIV, a woman of great beauty, died suddenly at
the age of 26, and it was generally believed that she had
been poisoned by powder of diamonds mixed, instead of
sugar, with strawberries.

With the exception of gall-stones and enteroliths, foreign
bodies rarely cause obstruction of the bowel. Nevertheless
a medical man once told me the following tale. A few

years ago he was seized with intense abdominal pain and persistent vomiting; and an eminent surgeon, having diagnosed acute intestinal obstruction, advised immediate laparotomy. But the patient, while awaiting his operation, remembered a lump of cheese hastily swallowed the day before, and with excellent judgement decided that an ounce of ol. ricini would probably relieve his symptoms. A body is most likely to lodge in the lower ileum or caecum, and ulceration of the bowel may lead to a perforation and death, or may induce the formation of an abscess, upon the evacuation of which the foreign substance is safely discharged. Roose,[20] in the *Lancet* of September 9th, 1893, illustrates the passage of an iron teaspoon from the colon through the abdominal parietes. It had been swallowed five weeks before. Intestinal diverticula delay the passage of a foreign body. I have found a fish-bone in a duodenal diverticulum, a piece of paper, such as one finds adhering to ginger-cake, 1/2 by 1/2 in. in the crater of a gastric ulcer, small shot in the lumen of an appendix, and a rabbit's rib projecting through the mucous membrane of the rectum into the cavity of an ischio-rectal abscess.

Inanimate objects are introduced into the rectum to relieve the persistent pain of haemorrhoids, or the intolerable itching of pruritus ani and to gratify abnormal sexual desires. Anal discomfort is often alleviated by the presence of a metallic substance in the rectum, and there is at present on the market a cone-shaped body named "the little wonder" which seldom belies its title.

Poulet[21] gives a comprehensive list of foreign bodies found in the rectum, among which he describes an ale glass, crockery, a fork, the handle of a shovel, a preserve jar, a pepper-box, and a bottle of mushrooms.

Lockhart-Mummery[22] quotes several interesting cases: a monk who to cure a violent colic, introduced into his fundament a bottle of "l'eau de la reine de Hongrie" with a small opening in its mouth by which the contents, drop by drop, could enter the intestine, a Dutch peasant who inserted a smooth stone, 900 grams in weight and 17 cm. long, to relieve a prolapse; a convict at Brest, who introduced a box of tools, which was found in the transverse colon, and contained a piece of gun-barrel, a screwdriver, a saw for cutting wood, and several other instruments.

Cases of poisoning have been reported from phosphorus matches and tobacco.[23] A convict, admitted to Liverpool prison in excellent general health, was found four hours later in a state of collapse with nausea, vomiting, and paralysis of the legs. He had secreted an ounce of cut Cavendish tobacco in his rectum to convey it past the searchers. Nor has the rectum been immune from the methods of torture which darken the pages of mediaeval history.

Female Genito-Urinary System

Transuterine insufflation of the Fallopian tubes, the watchspring pessary, the Grafenberg silver ring, and other ingenious devices enable gynaecologists to maintain an even balance between fertility and sterility. Conception is no longer left to chance, and future generations will doubtless find that the determination of sex is in accordance with their wishes. Foreign bodies, inserted in the treatment of pelvic disorders, have escaped the memory of both doctor and patient. Poulet[24] mentions an interesting case a pregnant woman was examined by a doctor, who suspected carcinomatous degeneration of the neck of the uterus. Capuron, who was consulted, did not believe that the state of the woman's health warranted the diagnosis, and on further examination the "growth" was found to be a sponge, which had been previously introduced into the vagina. There are many cases on record in which pessaries have been retained in the vagina for thirty years. Glass pessaries are not changed by the vaginal secretion, but metal instruments are eroded and become encrusted by calcareous salts. A broken glass douche nozzle, left in the vagina by a careless nurse, has been known to cause temporary domestic unhappiness. Sutures, filiforms, and pieces of catheter and rubber tubing may provide a nucleus for stone formation. A doctor in the North of Scotland, on investigating a calculus removed from the bladder of a woman, found it had formed round a condom *à l'envers*—no history of intercourse by the urethra was forthcoming.

Masturbation is responsible for the motley array of foreign substances found in the genito-urinary system. Feathers, chewing gum, and hair-pins present interesting problems to the cystoscopist; and Cabot[25] describes a case in which a straw, passed in through the urethra, had become engaged in one of the ureters for part of its length.

Pearse[26] mentions a woman, aged 36, who suffered from menorrhagia for ten days and was in a state of great prostration. He found a silk bobbin, which the patient had introduced fourteen years before. She had suffered from attacks of peritonitis and the presence of a urethro-vaginal fistula. She had been married twice, and had been cared for by physicians, but the existence of a body 3/4 inch long had not been noted.

Large objects become impacted in the vagina. Barnella of Innsbruck removed a drinking glass from the vagina by means of a pair of small obstetric forceps. Cloquet[27] describes the necropsy on a woman who had a pewter goblet in her vagina, and notes that lead oxide was found in the gangrenous debris.

Crochet hooks, scissors, knitting needles, and catheters have been used to procure abortion, and death has not infrequently followed perforation of the uterine wall, haemorrhage, and septic peritonitis.

Glaister[28] reports the case of a woman who passed a gold penholder with a sharp grooved point into her uterus. It slipped from her hand and disappeared. A few days later she was seized with intense abdominal pain; the abdomen was explored and the penholder was found beneath the diaphragm.

Zuhmeister[29] describes the case of a woman who used the twig of a tree to perforate the matrix. She thrust it so forcibly into the uterus that the wall was perforated. Although 6 inches long and the thickness of a goose feather, the branch remained for five months in the pelvis without causing any inconvenience, and was finally discharged per rectum.

A description of foreign substances entering the female genital system would be incomplete without reference to the peculiar belief, prevalent among widely different and distant races, that impregnation may follow the entrance of a foreign substance in place of the male spermatozoon. It was no unusual thing for the ancient Egyptian kings to deduce their ancestry from the immaculate conception of a virgin, and to imagine that God (Āman Rā) was their father. The monarchies both of the Huns and of the Moguls were erected on the basis of such superstition, and the miraculous conception of Zingis, ascribed to a virgin, raised him above the level of human nature. Other races give a more explicit history, and state that imprudent exposure to the rays in bathing, or to the dripping of a stalactite has caused a woman to become pregnant. In *The Lady of the Lake* Sir Walter Scott vividly describes the birth of Brian following the impregnation of a virgin mother by dust blown from the bones of the long-departed dead.

Male Genital System

The ancient custom of infibulation of the external genital organs was not uncommon among the Greeks, Romans, and Asiatics. Certain of the religious mendicants in India were condemned to a life of chastity; and in the hotter climates, where nudity was the custom, the person travelled about exposing an enormous prepuce ring, which was looked upon with adoration by devout women.

In September, 1929, a young man inserted his penis through a gold signet ring. He failed to remove it and when he consulted his doctor, the ring lay buried from view in the oedematous tissues of the penis, which was exquisitely tender and of a deep purple colour. After slipping a piece of fine tin-foil through the ring to protect the penis, I relieved his embarrassment and alarm by dividing the ring with nibbling forceps.

A few years ago a man inserted his penis into the neck of an earthenware hot-water bottle. He failed to withdraw it and, although he got rid of the greater part of the bottle by chipping it off with a hammer, he required the assistance

BROOKMANS PARK STATION (L.N.E.R. main line). Tavistock Square, W.C.1.

is doctor in removing the jagged stone ring which encircled penis and resisted all attempts at removal till fixed in a

n November, 1927 a boy was admitted to the Royal rdeen Hospital for Sick Children suffering from a cicatrix rounding the penis and a urethral fistula His doctor orted that he had been called to see the boy, and had oved a piece of string tied tightly round the penis The d had ulcerated into the urethra, and had almost severed body of the penis The boy suffered from nocturnal iresis

Other foreign bodies found in the male urethra in ate a prurient tendency Gross[30] found three caudal tebrae of a squirrel in the centre of a vesical calculus was discovered that the patient had practised urethral sturbation with the tail of this animal

Terrilon[31] describes the case of a man of 24, who introduced pencil into his urethra It remained there for fifteen days l then passed into the bladder Following successive empts to break the pencil he had violent chills and an ense evening fever On the thirty third day Terrilon oved the pencil by operation, but the patient died of a vesical abscess

THE HEALTH OF LONDON

REPORT FOR 1930

The annual report[1] of London's county medical officer of ealth and school medical officer, Dr F N Kaye Menzies, hows once again how wide is the province of the chief ealth official in a great city From vital statistics to rivate wells, from the purity of milk and water to precautions against sewer explosions, and from the provision of rescue homes to handicraft classes—all these and many other matters come under his supervision It is no mall tribute to Dr Menzies and his staff, as well as to he progress of preventive medicine, that the death rate in he civil population reached last year so low a figure as 1 6 per 1 000 Every cause of death showed a lower igure than in the previous years, with the exception of measles The spring of 1930 included the end of the biennial epidemic, and therefore the statistics for that year show a large number of deaths from respiratory complications Since another epidemic of measles is due this winter, it is of interest to note the relatively enormous death rate that this disease entails the deaths in 1929 were 206, and in 1930 they numbered 1,027 Even this epidemic was less severe than that of 1928

Vital Statistics

The population in the County of London at the time of the census in April last is given as 4,396,821, an increase of about 100,000 on the census figure in 1921 The birth rate, as in the previous year, was 15 8 per 1,000—the lowest on record On the whole, the year 1930 was a healthy one, epidemic diseases were comparatively rare, and mortality from influenza was particularly low Conditions were favourable to infant life, the deaths under 1 year of age being only 59 per 1,000 births There was, however, a marked increase in deaths attributed to cirrhosis of the liver The mild type of small pox continued unabated, but there were only ten deaths No virulent small-pox occurred The case mortality for diphtheria was 3 3 per cent, a slight increase, which may perhaps indicate a slackening off in the use of anti toxin—a measure which was stressed by the Ministry of Health in 1922 and 1923, with the result that the death rate diminished notably in 1923, 1924, and 1925 There were 293 notifications of puerperal fever and 740 of puerperal pyrexia during the year—a slight decrease on 1929 The death rate from puerperal fever and other accidents of childbirth was 3 33 per 1,000 births, rather more than half being due to puerperal fever

One fatal case of anthrax is reported in an employee at a flour and grain wharf, its origin could not be traced Of 88 notified cases of cerebro-spinal fever, 75 were confirmed, and 51 of these patients died, a further 29 deaths occurred in unnotified cases or cases notified in 1929 There were 45 confirmed cases of adult encephalitis lethargica, of these, 16 patients died The whole of the special accommodation for these cases at Winchmore Hill (50 beds) was occupied at the end of the year and so great was the number waiting admission that 115 more beds are to be provided The report of the school medical officer, which appears as a separate publication[*] this year contains a survey of the disease among children. There were 4 deaths among 30 proved cases of polio-myelitis and polio encephalitis

The year 1930 was marked epidemiologically by one unprecedented disease in the town—yellow fever A fatal case occurred in a laboratory worker who was engaged in research on this disease, there were two other severe cases and three milder cases, but these patients recovered It was thus shown that species of mosquito other than *Stegomyia fasciata* can carry the disease, that the infection can penetrate the unbroken skin, and that laboratory work which involves handling apparatus contaminated with infected blood is extremely dangerous The investigation was therefore stopped

There were 6,908 deaths from cancer—a slight increase—with a death rate per 1,000 of 1 57. The tuberculosis death rate was 0 87 per 1,000 living

Common Lodging Houses

The report contains an interesting historical survey of the attempts made to provide lodgings for seamen and the peculiar difficulty of the Chinese seamen There are now 152 licensed common lodging houses, and 22 seamen's lodging houses, the supervision of these entailed 7 582 day visits and 212 night visits by the inspectors during the year Opium smoking has now practically ceased in the lodging houses, owing to the operation of the by laws and the Dangerous Drugs Acts A census of homeless persons in the city, taken on February 14th—a cold night—showed 54 men and 25 women in the streets 14 855 persons in common lodging houses 631 men 117 women, and and 18 children in free shelters and homes 724 men and and 18 children in free shelters and homes 724 men and 16 women in casual wards and 5 014 men in Rowton houses There has been a steady decrease in the number of homeless persons except for the low figures obtained during the latter years of the war Apparently very few women are really homeless nowadays The lodging houses are very much cleaner than they used to be, and there was

[1] London County Council Annual Report of the Council 1930 Part I vol iii London P S King and Son Ltd 1931 No 2880 (1s)

[*] See *British Medical Journal* October 3rd, p 612.

no occasion during the year to make formal examination of a person suspected of being verminous.

Milk, Water, and Food

The routine investigation of samples of milk was transferred on July 1st last from the laboratory where it was formerly done to the council's own laboratories at Park Hospital; this change produced a saving of approximately £650 per annum. It is not surprising to learn that the number of cowsheds in the county has diminished—from 738 in 1888, the year of the council's inception, to 50 in 1930. It is, perhaps, surprising to learn that there are still so many, and that some of them are situated in Stepney and Bethnal Green; these are necessary for the supply of milk to Jews in accordance with the rules of their religion.

The bacteriological laboratory examined specimens of tap-water and main supply, and found that the water of London maintains its high standard of purity. The chemical laboratories have examined many samples of stores, and specifications have been revised so as to bring them closely into touch with modern conditions and requirements. The volume of analytical work has greatly increased, and the duty of examining drugs has been added to the work of the council under the Local Government Act, 1929. The samples investigated during the year cover a wide range, including air, disinfectants, various metals, foods of all kinds, water, wax, soap, fertilizers, condensed milk, oils, shampoo preparations, and boiler deposits. Some of the milk supplied to children in elementary schools was found to be rather dirty, generally owing to careless handling, though its composition was usually good. Quite a number of hospitals and other institutions in the London area still have private wells, and forty-five analyses of the water were made during the year. Experience with outdoor baths has shown a great improvement when the water is filtered and chlorinated; a clear, practically sterile water can be maintained for months, despite the use of the bath by large numbers of unsupervised bathers.

Venereal Disease and Tuberculosis

The London and Home Counties scheme, which came into operation in 1917, has continued to work well, and the clinics have shown an increase of new cases on the previous year. A very large number of non-venereal patients come for examination, and the number of pathological tests made has increased from about 17,000 in 1917 to nearly 160,000 in 1930. During the year the clinic at the London Hospital was transferred to the council; now run as an all-day clinic (every day of the year) under the directorship of Dr. T. Anwyl Davies, it has proved an unqualified success.

The council provides residential treatment for all tuberculous patients who are likely to benefit from it, while chronic and acutely ill cases are accommodated in the council's hospitals. The Local Government Act, 1929, makes it possible for the council to distribute its patients more satisfactorily than it could before. Nearly 6,000 adult cases were recommended for residential treatment during 1930, and just under 5,000 of these were sent to sanatoriums or observation beds. Of 1,121 children recommended for treatment, 1,068 were accepted. A number of patients were also sent to Papworth and Preston Hall; the council has arranged to pay the difference between the patient's value as a wage-earner and his cost of maintenance. The Burrow Hill Colony at Frimley, which was reorganized in 1929 for youths between 14 and 19 years old, maintains about 40 beds for the council and trains specially selected boys in gardening, with a view to their future employment as "improvers" in the council's parks. Particulars obtained in 1929 of the 1,324 surviving adult patients who had been discharged from treatment in 1924, showed that 65.4 per cent. of the A and B1 cases, and 55.6 per cent. of the total, were at work. Special efforts are made to provide suitable employment for all ex-patients who are fit for it; for those unfit to do ordinary work there are handicraft classes in several boroughs; the council pays the instructor, and other expenses are paid by voluntary contribu-

Mental Deficiency

At the end of the year the council had 3,712 mental defectives in its institutions, 100 under guardianship, 2,592 under supervision, and 36 in places of safety awaiting action. Special attention was paid during the year to the period of life at which defectives were brought to notice; practically all the feeble-minded were notified by the Education Committee when they left special schools for the mentally defective. As would be expected, very few of this group were notified under the age of 7, and very few of the idiot group over the age of 16. An analysis has been made of 80 feeble-minded and 50 imbecile persons taken at random as they were dealt with under the Mental Deficiency Acts, with a view to finding out the cause alleged by the parent. In the feeble-minded group the list is headed by fright and worry during pregnancy and injuries in infancy. The first of these also appears much more often than any other cause in the imbecile group. In 70 per cent. of this group the alleged cause depends on extrinsic factors, whereas in the feeble-minded group the percentage is only 42.5. This suggests that the parents of imbeciles are often more intelligent than those of the feeble-minded. Of all the causes suggested, none could be taken as a serious contribution to etiology. The investigation also showed a larger proportion of congenital defects and abnormalities in imbeciles than in the feeble-minded, many of them being closely associated with the defect. Apart from squint and dental disorder, no undue incidence of disease was found among the children attending the occupation centres of the London Association for Mental Welfare.

Miscellaneous

The report gives a table classifying the cause of blindness in both sexes. The largest group was due to internal inflammations of the eye, which are more common in men than in women; choroiditis and choroido-retinitis are almost twice as common in males, whereas iritis and irido-cyclitis are twice as common in females. Senile changes, the next large group, are much more often found in women, no doubt partly because of their greater longevity.

Of the 5,000 certified midwives with London addresses, 900 gave notice of intention to practise in the county during the year. Of the 284 cases of puerperal fever investigated during the year, 62, with 11 deaths, were in the practice of midwives, and 88, with 19 deaths, in the hands of medical practitioners. Of 760 cases of puerperal pyrexia, 154, with 16 deaths, were in the hands of midwives, and 150, with 11 deaths, in the hands of doctors. In midwife practice there were 1,369 cases of inflamed eyes, of which 321 proved to be ophthalmia neonatorum; 293 other cases were not notified by midwives. Special courses of demonstrations and lectures were provided for midwives.

During the year forty-two nursing homes applied for registration; eight applications were withdrawn when the council's requirements were explained, and registration was refused to two others. On the whole, the homes have been satisfactory, and there has been considerable improvement in general cleanliness and orderliness. At the end of 1930 the council had under inspection 1,773 homes for infants, and in a number of cases overcrowding and sanitary defects were notified and put right.

Automatic devices for detecting poisonous and explosive gases were put to the test, and it was found that they required manipulation by a skilled man, and that, for purposes of detection only, the ordinary miner's lamp was better in the hands of workmen than these elaborate devices. The air in the river subways has been systematically tested; the average carbon monoxide content in Blackwall was 21.5 parts per 100,000 under the worst conditions, occurring about 10 a.m. on weekdays in summer. New fans were therefore installed in September.

Finally, to complete its remarkable catalogue of activities, the council has undertaken observations of visibility from the County Hall at midday. It is hardly surprising to learn that the visibility is greatest in [illegible] and September.

MOTOR CARS FOR 1932

THE OLYMPIA SHOW

[From our Motoring Correspondent]

(*Concluded from page 716*)

Although a general reference has already been made to the downward tendency of car prices, and, where these have not been changed, to the better value offered than last season, it may not be without interest to deal a little more fully with the price question in order to give some idea of the wide selection that is available to medical men.

Prices for 1932

Last year the figure of £450 was taken as the outside limit which the average doctor was likely to desire to pay. This year, as a result of a combination of circumstances—the many reliable and convenient cars available at a lower figure, coupled with the need for economy owing to reduced incomes and higher taxation—the outside limit may now be safely lowered to £350, although this is not to say that more expensive cars are not worth every penny that is asked for them.

Beginning at the lower end of the scale, there is a choice of five of the "junior" class of car, the cost of any of which does not exceed £150. The number of vehicles available in the £151 to £200 category has increased from fourteen to twenty-two, and includes such well-known productions as the Morris Cowley and Morris Major, Rover, Ford, Austin "Twelve-Six," Citroën, Renault, and the Standard Big and Little "Nines." At £201 to £250 the number of models has dropped from fifteen to twelve, seven with four-cylinder and five with six-cylinder engines, notable productions in this group being the 10–30 h.p. Fiat and the 12 h.p. Rovers and Singers. Six-cylinder cars also predominate in the £251 to £300 group, numbering thirteen, compared with only nine with four cylinders. Prominent among them are the Armstrong-Siddeley 12 h.p. three- or four-speed cars, the new 10 h.p. Crossley, the 15 h.p. Morris Oxford, the 16 h.p. or 21 h.p. Hillman Wizard, the 17 h.p. Vauxhall Cadet, the Riley "Nine," the 15.7 h.p. Wolseley, and the Austin 12 h.p. four-cylinder and the "Sixteen-Six." Finally, in the £301 to £350 category there is a choice between eleven makes of cars, all, with one exception, of the six-cylinder type, including the new Star Comet 14 h.p. and the 17.7 h.p. Morris Isis. While these prices relate to the standard saloons, the majority of which are now provided with sunshine roofs without extra charge, most manufacturers are including a car with a coupé body and dickey seat in their respective ranges. This type generally costs a little more than the standard saloon.

In connexion with prices it may be added that Messrs. Mann Egerton and Co., who cater specially for doctors in London as well as at their four establishments in the Eastern Counties, have just issued a handy 1932 *Car Buyer's Guide*. In this the makes of cars are set out in alphabetical order, with descriptions of the various types of coachwork available. The most popular cars are dealt with exhaustively, and particulars are given of cars which can be specially recommended for professional and private use by medical men.

More British Cars

Continuing a brief review of the principal British cars on the market, the Alvis Company is still building three sizes of chassis—12–50 h.p. four-cylinder and "Sixteen" and "Twenty" six-cylinder—only slight detail improvements having been found necessary. This applies also to the Crossley Company's 16 h.p. and 20 h.p. six-cylinder vehicles. The chief new departure of this concern, as has previously been mentioned, is the introduction of a high-grade 10 h.p. four-cylinder model, the prices of which range from £265 for a family saloon to £310 for a semi-sports coupé. The Star Company of Wolverhampton, while continuing to build only six-cylinder cars, has added a new Comet "Fourteen" to its range, this being priced at £345 either as a saloon or as a coupé. Among its features, common to the 18 h.p., 21 h.p., and 24 h.p. models, are a system of four-wheel jacks permanently attached to the chassis, which has "one-shot" lubrication, a four-speed silent-third gearbox, and a patent signalling window for the driver.

Morris Cars

No report of the Show would be complete without a reference to the cars of the Morris Company, probably the most widely used of all vehicles in this country. Its 1932 programme is notable for the extended range, as well as for several improvements, and, above all, for slightly lower prices. Important changes applying to all models are a new design of radiator, wider bodies, Pytchley sliding sunshine roofs, "eddy-free" fronts to all saloons and coupés, Lockheed hydraulic four-wheel brakes on all but the "Minor" models, and, on all six-cylinder vehicles, automatic shutters to the radiators, and four-speed, twin-top gearboxes. Those requiring a car moderate in first cost and subsequent maintenance will be interested in the new Morris Family Eight, which is an enlarged edition of the Minor, its wheel base of 7 ft. 7 in. allowing a body with ample room for four persons to be mounted on the chassis. In addition to a saloon at £152 10*s.* there is an attractive coupé at £175. The Cowley has been improved in many ways, and, as previously mentioned, may now be had with either an 11.9 h.p. (£12 tax) or 14–32 h.p. (£14 tax) four-cylinder engine at the one price, ranging from £179 10*s.* for the fixed-head saloon to £190 for the coupé. The 14 h.p. six-cylinder Morris Major has been largely redesigned, and is now available with five styles of bodywork, at prices from £199 to £245. A favourite with medical men is the 15 h.p. six-cylinder Morris Oxford, which has not only been improved, but has been reduced to £255 for the saloon and £275 for the coupé, both with sunshine roofs. For those in need of a car of greater power and with more roomy bodywork there is the 18 h.p. Morris Isis, to the range of which a sports coupé at £350 has been added.

The Rover and the Standard

Although the new Rover 7 h.p. Scarab car, with two-cylinder air-cooled engine at the back and designed to sell at the low figure of £89, is an interesting production, it is too small to appeal to many doctors. On the other hand, the 10–25 h.p. four-cylinder Rover, built on what may be termed normal lines, is attractive from the point of view of price (from £179 upwards) and from the sturdy, up-to-date character of the construction and the neat bodywork. This company has introduced a 13 h.p. light "six" known as the "Pilot," the saloon of which costs £225 in coachbuilt form and £5 more with Weymann bodywork.

A make of car that has proved extremely popular during the past season is that of the Standard Motor Company. Four models are being produced, each of which will appeal to the medical profession. Where first cost is a consideration the Little or Big "Nine" four-cylinder will be found up to date in every respect. The Little "Nine," which sells at £155, has a three-speed gearbox, while the Big "Nine," which costs another £50, not only has a larger engine and bodywork, but is equipped with a four-speed, silent-third change-speed gear. On the six-cylinder side there is a "Sixteen" at £235 and a "Twenty" at £325, both of which will well repay careful study.

Other British cars to which attention may be drawn are the 7.9 h.p. and 8.9 h.p. Triumphs and the 12 h.p. six-cylinder Scorpion made by the same Company; the 17 h.p. Vauxhall Cadet, which has now a three-speed synchro-mesh gearbox, and the 12 h.p. Hornet and 16–60 h.p. Viper cars of the Wolseley Company: both of these are six-cylinder vehicles, the first-named ranging in price from £160 to £245 and the larger model from £285 to £309.

American and Canadian Cars

Although there is a falling off this year in the number of American and Canadian cars on the British market, most of the well-established types remain. Occupying a

leading place among them is the Buick, the three models of which are all fitted with "straight-eight" engines. The most popular type is the 26 h.p. Dominion five-seated saloon which, listed at £398, is now fitted with a three-speed synchro-mesh gearbox as standard, instead of at an extra charge. The Chrysler Company is continuing to produce four-, six-, and eight-cylinder cars. The cheapest model is the 16–56 h.p. Plymouth at £275, while a popular type is the 20–63 h.p. six-cylinder De Soto at £325. A familiar American car is the 18.2 h.p. Essex Challenger, which has not only been improved in detail, but is now being offered at prices ranging from £195 for the five-seated saloon. Although supplied only at an extra charge, an innovation on the Essex cars is a free-wheeling device controlled by a separate auxiliary lever, which is stated to render gear-changing an easy matter, even for novice drivers.

Popular Italian and French Cars

Among the well-known Italian cars is the Fiat, which is now being produced or assembled in this country. Attention is being concentrated on a 10–30 h.p. four-cylinder chassis fitted with six types of bodywork, and two models of 18–55 h.p. six-cylinder vehicles. Only detail changes are noticeable, these being chiefly directed towards rendering the brakes more powerful, improving the springing, and making the engine accessories more accessible. Among the oldest of the French cars on the British market are those of the Peugeot Company; for 1932 only 10 h.p. four-cylinder models are being offered, one with the usual form of suspension by semi-elliptic springs, and one in which the front road wheels are independently mounted on a transverse spring. Prices for saloons range from £169 to £209. The Renault firm, in keeping with the tendencies of the times, has reintroduced a "Ten" four-cylinder car and added a 12 h.p. "Six" to the range, both of these being offered at attractive prices. Cars of higher power are also made, the largest being a 40 h.p. "straight eight." Hitherto the Renault cars have always had a radiator of the firm's own design, but this has now been altered to the more popular shape.

Although of French design the Citroën cars, which are popular with many medical men, have been built in this country for some time. Both the four- and six-cylinder models are being produced with slightly larger engines, while many detail improvements have been introduced. A notable change is the increase in the wheel track, which enables much larger and wider bodies to be fitted. The range now includes seven-seated saloons and limousines.

Special Motor Bodywork

Despite the fact that what may be termed standardized bodies as supplied by the car manufacturers are of excellent design and well equipped, there is a tendency, even among the makers of the popular-priced vehicles, to supply a chassis on which purchasers may have mounted the bodywork of their own choice. Thus, a feature of the exhibits of the carriage-builders is the increasing attention given to bodies for relatively small cars, among the makers being the New Avon Body Company and the Swallow Coachbuilding Company. While saloons are the most numerous, there is a noticeable increase in closed and drop-head coupés, a good example of the latter being shown by Martin Walter, Limited, on an Austin Sixteen-Six chassis. Mann Egerton and Co. are among the firms devoting attention to the construction of special bodywork for doctors' use; this year, however, all the cars they exhibit are of relatively high horse-power. The smallest is a 16 h.p. Sunbeam, with an attractive six-light saloon body, the front seats of which, although of the twin-bucket type, are so constructed that they can be lined up to accommodate three persons.

The Accessory Section

One of the features of the gallery section at Olympia is the remarkable variety of fittings now available for use on motor vehicles. Nowadays it has become the fashion to mount the electric horn on the front of the radiator; of these horns there are several patterns. Although the dazzle problem has not been completely solved, there are many designs of dipping lamps and reflectors which diminish the trouble. The numerous exhibits of modern forms of ignition equipment indicate that no pains are being spared to produce components that shall give reliable service. A similar remark applies to sparking plugs, among which the Lodge and K.L.G. are prominent. Lodge Plugs, Limited, show duplicates of the plugs used on the world's fastest aeroplane and motor boat.

Winter Motoring Requirements

Held opportunely in the late autumn, the motor show serves to demonstrate the many useful aids to winter motoring that are now available—for example, the various stoves and radiators for heating the garage in winter, so that no trouble may arise from the freezing-up of radiators and cylinder jackets. Gamage's stand shows a number of these appliances, as well as radiator muffs, which doctors will find useful in very cold weather. The only alternative to heating the garage during the winter months is to add some form of anti-freezing glycerin compound, such as that known as Zero, to the water in the radiator. At a time when fogs and snow may be expected there is much interest in the exhibits of special fog lights and chain attachments for tyres, such as the Parsons, the Grippit, Griff, and Pladdey, any of which can be obtained from a general motor accessory firm. It should be borne in mind that a spare set of electric bulbs carried on the car may save much inconvenience should any failing in the lighting system occur.

Finally, a reminder may be given of a legal requirement that does not yet appear to be generally known—namely, that all private garages, even if the only petrol in them is that in the tanks of the cars, must be provided with a supply of sand, or with a portable fire extinguisher, of which there are many patterns available at a relatively small cost. Although the risk of fire in private garages may not be great, negligence in this matter may lead to difficulties with the motor insurance companies.

C. J. W.

Scotland

Royal College of Physicians of Edinburgh

As announced formally in another column, the celebrations arranged in connexion with the two hundred and fiftieth anniversary of the founding of the Royal College of Physicians at Edinburgh on St. Andrew's Day (November 30th), 1681, will not now take place. At a meeting of the Fellows of the College, held last week, it was resolved that in view of the national situation the celebration of this anniversary should be indefinitely postponed. The honorary Fellowship of the College will be conferred on certain distinguished physicians as originally arranged.

New Edinburgh Professorship

The inaugural lecture of the recently established Edward Clark chair of child life and health at Edinburgh Edinburgh University was delivered on October 16th by Professor Charles McNeil, the first occupant of the chair, in the anatomy theatre of the University. Taking as his subject "The scope and need of teaching in child life and health," Professor McNeil said that the gift of this endowment by the trustees of the late Mr. Edward Clark had raised the status of an important medical subject, and given it a secure position in that medical school. The name of the chair was well chosen, for it included not only diseases of children, but the child himself, and this wider scope corresponded to the wider duties now undertaken by the doctor in his practice. One of the most important causes of the advancement of the study of disease in children had been the foundation of special hospitals for children in the second half of the nineteenth century. The Great Ormond Street Hospital for Sick Children in London had been founded in 1852, and a few

ALWAY
BOOKMAN'S PARK STATION (L.N.E.R. main line).
Tavistock Square, W.C.1.

years later, in 1858, the Edinburgh Children's Hospital was opened on a site which was now the western boundary of the Royal Infirmary. It was a common remark that the sick child could not tell what he felt wrong with him, and that this must create special difficulty for the doctor. This seeming disadvantage, however, might be an advantage in throwing the doctor back upon a more careful clinical examination and saving him from misleading information. The main difficulty in regard to children was that the reactions of the child's body to disease were often different from those in the adult; thus it was rare to find in the child, with its active growing tissues, diseases such as pernicious anaemia, cancer, ulcer of the stomach, and those chronic degenerations of the heart and blood vessels that beset the worn-out body in later years. On the other hand, the child was subject to some diseases from which the full grown body was more or less immune, such as the infectious diseases of childhood, inflammatory infections of the bones, meningitis, and other inflammations of the brain and cord of which infantile paralysis was a good example. It was a fairly true general statement that mature age was the time of degeneration, while childhood was the time of bacterial infection. There were various important diseases that were common both in childhood and in maturity, but assumed a different clinical form in the child. The best example was tuberculosis, which in mature years predominated as a slow, progressive inflammation of the lungs, but in the child assumed a great variety of quite different clinical aspects, although the causal tubercle bacillus was the same and entered the body by the same channels. The teaching of this subject ought to give a clear account of the fundamental processes of growth, both physical and mental; it had to cover the common diseases of childhood, both surgical and medical, but in addition to disease it ought to deal with the care of the child in health. He did not know of any medical school in which there was a longer course of teaching in this subject than three months, but he thought that the foundation of this chair offered an opportunity to review the teaching programme. In his opinion the health of children was far more satisfactory to-day than it was fifty or even twenty years ago. This improvement had been effected largely in two ways—namely, by the great reforms in public sanitation and by the diffusion of knowledge among mothers regarding the care of the child. There was still a great amount of sickness and death in the first few years of life which he believed to be largely preventable. The most hopeful work along this line was to study and teach the rules and conditions by which the health of the child might be preserved, and this task of educating the people belonged to the doctor and the nurses engaged in medical practice. The foundation of this chair should be a stimulus to more active study and to more efficient teaching.

Scottish Universities' Representation in Parliament

The first members to be elected to the new Parliament were the three representatives of the four Scottish Universities, who were nominated at a meeting held in the Upper Library Hall of Edinburgh University on October 13th, Sir Thomas Holland, Principal and Vice-Chancellor of the University, presiding, and acting as returning officer. For health reasons Sir George Berry, M.D., who has represented the Universities as a Unionist member for several years, did not seek re-election. The nominations lodged were those of John Buchan (Unionist), who is well known as an historian and author, and has acted as a representative of the Scottish Universities since 1927, Dugald McCaig Cowan (Liberal), at one time head master of North Kelvinside higher grade school, who has published a number of books on educational subjects, and has represented the Scottish Universities since 1918; and A. Noel Skelton (Unionist), a member of the Scottish Bar, who has represented Perth in Parliament for the past seven years, and on the recent formation of the National Government was appointed Under-Secretary of State for Scotland. After the prescribed time for lodging nominations had elapsed, Sir Thomas Holland said that as no more than three nominations had been received for the three seats, he declared Mr. Buchan, Mr Cowan, and Mr. Skelton duly elected members of Parliament. He added that as no new candidate had been nominated, a sum of approximately £1,000 in postages alone would be saved to the Universities.

Special Schools in Scotland

The Dalton special school for invalid children, situated between Blantyre and Cambuslang on the outskirts of Glasgow, was opened on October 16th by the Rev T F Harkness Graham, chairman of the county council medical services subcommittee. Sir Henry Keith, chairman of the Lanarkshire Education Committee, presided. There was no branch of education, said the Rev Harkness Graham, in which more hopeful advance had been made than in the provision afforded for teaching those who were physically or mentally handicapped. Dr John Jardine, assistant secretary to the Scottish Education Department, described the school as admirably equipped for all the purposes for which it was intended. He thought that these special schools which were being built in Lanarkshire compared favourably with any in the world. At the present time in Scotland provision was made for some 5,500 children with physical defect, and for some 3,800 who had some mental defect. This was distinctly in advance of what had been done in England. These special schools had a great influence on Scottish education, and had considerably modified the system of education for the normal child, for it had been discovered in teaching the mentally backward that a great deal could be done in educating the child by way of hand and eye training, so that the conclusion had been reached that this method of training should be introduced to a larger extent in the education of the ordinary child. The Dalton special school is the fourth of this type in the county of Lanarkshire, and has been built at an estimated cost of £26,000. It is of one story, triangular in plan, with eight class rooms and accommodation for 230 children. The scheme of teaching includes departments for woodwork, metal work, cobbling, cookery, laundry, and housewifery, and the class rooms all face south. The rooms are constructed on the open-air principle, with baths and dressing rooms. A rest shelter and a remedial gymnasium are also provided.

Residence Hall at St. Andrews

The University Court of St. Andrews University has opened Deans Court as a residence for students, supplementing the accommodation already provided at St Salvator's Hall. The building was opened for occupation on October 9th. It occupies the site of the ancient lodging of the archdeacon of St Andrews, opposite the ruins of the cathedral, and is one of the most picturesque dwellings in this old university town, having an old world air and a large garden. It accommodates some fifteen students, and is under the supervision of the wardens of the neighbouring St Salvator's Hall.

Gifts to Scottish Infirmaries

The directors of Arbroath Infirmary recently made a public appeal for increased support for this institution in view of a probable financial deficit on the current year's account. It was stated that since the extension of the Infirmary at a cost of £18,000, the expenditure had increased greatly and the committee was now faced

with a debt of £2,480, so that if greater public assistance was not forthcoming the hospital would have to be partially closed. As a result, Mr. W. W. Webster of Denley, president of the Infirmary, has given a donation of £1,000 to its funds. A sum of £1,050 has been presented to the Royal Infirmary at Inverness by an American visitor to the Highlands of Scotland, Mr. E. Hulsert Litchfield, in memory of Mrs. Edward H. Litchfield of New York.

Ireland

Vital Statistics for Northern Ireland

A review of the vital statistics for Northern Ireland has recently been published by His Majesty's Stationery Office. The estimated population of Northern Ireland in 1930 is given as 1,244,000, a decrease of 2 per cent. since 1923. During the fifty years 1841–91, the population of the Province declined by some 25 per cent.; then followed a period of thirty-five years during which small increases occurred, the peak for this century being reached in 1922, when the population was 1,269,000. According to the report the present tendency towards decline seems to be temporarily checked, owing to the less favourable conditions affecting emigration to the United States and to the Dominions. Such indications as there are point to a probable maintenance of the present population for a period of years, or, at any rate, to only a small decline during the next decade. Except for the violent fluctuations which took place during the war and immediately afterwards, the birth and death rates have declined fairly steadily throughout the past twenty-five years. The birth rate per 1,000 of the population last year was 20.8, and the death rate 13.8. It is noteworthy that the standardized death rates for 1925–27 were about 35 per cent. lower than those for 1890–92. Attention is drawn to the relatively high death rates for females in Northern Ireland. In the years 1926–29 they were, on an average, about 96 per cent. of the rates for males, the corresponding ratio for England and Wales being about 81 per cent. The extent of the failure to make use of existing medical facilities is indicated by the number of uncertified deaths, no skilled medical advice having been obtained during the last illness. In some counties in Northern Ireland the proportion of such cases exceeds 25 per cent. of the total. In the present generation there has been a material decline in the death rate among infants, both male and female. The death rate among male infants is still the higher. In spite of high rates of unemployment the marriage rate has been well maintained in the Province in recent years, but the number of Roman Catholic marriages in the period 1924–28 was apparently the lowest recorded in Northern Ireland. While only 6 per cent. of the marriages in the Province take place in registrars' offices, there is a marked tendency for the proportion to increase. Comparison with the Irish Free State shows that the fertility of married women is less in Northern Ireland. During the past thirty years the cancer death rate has increased by over 40 per cent., although it is considerably lower than the rate in Great Britain. During the same period the cancer rate in the Irish Free State has increased by 80 per cent., but it is still below that for Northern Ireland.

Belfast Health Report

At a meeting of the Belfast Corporation Public Health Committee the medical superintendent of Purdysburn Fever Hospital reported that during the two weeks ended September 26th, 70 patients were admitted and 53 were discharged, leaving 137 patients in the hospital. The sanitary report for this period showed that 5,079 inspections had been carried out. Draft by-laws for the protection of meat from contamination were under consideration, and a copy of the draft by-laws was directed to be sent to each member of the committee and to the secretary of the Master Butchers' Association for their information. A letter was read from the Ministry of Home Affairs approving of the conditions of appointment of city veterinarian, and instructions were given that applications for the position should be invited by public advertisement.

Medical Witnesses and the Workmen's Compensation Act

In a recent case under the Workmen's Compensation Act in the Dublin Circuit Court, a medical witness asked the judge to require him only to give evidence on facts as he had been brought to the court by subpoena. The judge agreed that he was within his rights in his request, but asked why he was taking that course. The witness replied that he objected to the discourtesy of the injured man's solicitor, who wrote to his client telling him "to get a report from his doctor" instead of communicating directly with the witness by letter or otherwise. The judge agreed that the action was discourteous, and the witness, having made his protest, then elected to give all the evidence in his possession without restriction. Commenting further on the subject after the hearing of the case, his lordship said that without the co-operation of the doctors in these cases—assistance which was always generously given—the work of his court could not be carried on. Solicitors, he declared, should recognize that, and they should not ask a doctor to appear in court and give evidence for the ridiculous sum of £1 11s. 6d., but should arrange to give medical men appearing for their clients a reasonable fee for their expert opinions.

England and Wales

Vital Statistics for 1930

Part I (Medical Tables) of the Registrar-General's Statistical Review of England and Wales for 1930 is now on sale at H.M. Stationery Office, price 7s. 6d. net. Among the leading facts disclosed in this volume the following may be mentioned. The birth rate for the year 1930 was 16.3 per 1,000 persons living at all ages, the actual number of births registered being 648,811. The rate is the same as that for the preceding year, which was the lowest birth rate recorded since the establishment of civil registration in this country. The death rate was 11.4 per 1,000 total population, the lowest death rate recorded. It compares with 13.4 for the year 1929 (a year having an epidemic of influenza and a high mortality from respiratory and circulatory diseases), and a previous low record of 11.6 in the years 1926 and 1923. The favourable death rate is largely attributable to the less severe weather in the first quarter of the year, the difference for the two years being very marked, the first quarter of 1930 having a rate of 13.4, whereas the figure for the corresponding quarter of 1929 was 20.9. The deaths of infants under 1 year of age were equal to a rate of 60 per 1,000 live births, the lowest recorded for England and Wales. The previous low record was 65 for 1928, while for 1929 the figure was as high as 74. The rate of 60 in 1930 was, however, for the two sexes, the figures for the sexes separately giving as wide a difference as 68 for males and 51 for females, taken respectively on a basis of live births in the same sex. As regards specific diseases, the crude rate for cancer was 1,454 per million living, against 1,437 for 1929. If, however, allowance is made for differences in the age constitution of the population, the comparative mortality from cancer has been almost

AT ... PARK STATION (L.N.E.R. main line). ... Tavistock Square, W.C.1

ationary during the last few years. The death rate from uberculosis (all forms) further improved to 898 per illion living, the lowest figure recorded. The mortality f women from puerperal sepsis and accidents of preg- ancy and childbirth was 4.40 per 1,000 live births, com- ared with 4.33 in the previous year. Of the component gures, sepsis was again somewhat higher at 1.92, as gainst 1.80, but "other accidents of pregnancy and hildbirth" showed a slightly better figure at 2.48, against .53 for 1929. The rate for suicide again showed a small ncrease to 127 per million (the highest figure recorded) rom 126 in the previous year, the rate for males rising rom 183 to 185, and that for females from 73 to 74. Deaths resulting from accidental injury by mechanical ehicles on roads, as returned by H.M. coroners, were ,404 as against 4,492 in 1927, 5,251 in 1928, and 5,799 n 1929. Exclusive of collisions between two types of ehicles, the deaths caused by motor cars were 1,643 gainst 1,660 in the previous year; by motor van, lorry, tc., 1,273 against 1,162; by motor cycle, 1,286 against 1,162.

"Unity in Medicine"

At the opening meeting of the Pathological Society of Manchester Professor Fletcher Shaw gave the presidential address, entitled "Unity in medicine." To the present generation, he said, it seemed incomprehensible that anyone could reach the *Medical Register* without a training in medicine, surgery, and midwifery, and yet, until so recently as 1886, licences to practise these subjects separately could be obtained. The president then outlined the history of each of these branches, showing how widely separated they were in early times, and how how gradually approached nearer and nearer together, until at length the Act of 1886 allowed no man to be registered who had not been trained and examined in all three subjects. The factor which did more than anything to show the importance of a general training in the elementary sciences, in anatomy and physiology, and in all branches of medicine—no matter what licence the student aimed at—was the creation of private medical schools. William Hunter's in London was the most famous, and the popularity of this and similar schools compelled the hospitals to found schools of their own. In the provinces, Turner's school in Manchester was the first founded outside London, and it still existed in continuous succession as the Medical Faculty of the Manchester University. When once this fusion between these branches had been accomplished, it might have been expected that they would remain fused. Unfortunately, this was not so; all these subjects were still included in the students' curriculum, but during the period of fusion other forces were at work, which diverted the post-graduate work of these students, and tended to keep them in separate watertight compartments; these forces were the rapid advance in knowledge and the formation of special hospitals. The special hospitals did little harm at first, as the members of the staffs treated all types of patients in private practice, but gradually there arose groups of men interested only in special branches, who spent the whole of their post-graduate lives in the practice of that branch. This was bad for patients and for teaching, as each teacher tended to look at a subject from his own particular angle, and without reference to any other. This specialization affected even the basic subjects—anatomy, physiology, and pathology—and in many schools they were taught without any relation to each other or to the clinical subjects. With regard to the future, Professor Fletcher Shaw advised that more and more attention should be given to the teaching of anatomy, physiology, and pathology, and students should be encouraged to take an honours degree in physiology after passing the ordinary anatomy and physiology examination. The teachers of these subjects, however, should be chosen as much for their ability to teach as to do research work; they should themselves have received a good clinical post-graduate training, and during all their teaching career should keep in touch with clinical work, otherwise they lost contact with what was most required by medical students. No more special hospitals should be founded; only special departments of general hospitals. Many special hospitals were doing excellent work, and their old reputation was an asset. These should not be scrapped or their identity lost by amalgamation; rather, when rebuilding had to be carried out, a scheme should be formed whereby they became grouped together, each with its own name, funds, and lay board, but with complete freedom of medical service, so that members of one staff could be called in consultation with the others, and patients freely transferred. England, Scotland, and Ireland each possessed its Royal College of Physicians and of Surgeons, and now there was a College of Obstetricians for the whole country, each college with its own special regulations and tests. Candidates for hospital staff appointments in different centres reached their goal by different means; in some, stress was laid upon post-graduate clinical experience; in others, upon special qualifications. But no hospital or college required its candidates to produce evidence of post-graduate training in medicine as a whole. By a combination, these colleges could insist upon a broad general training in medicine for all candidates for consultant rank. A primary examination after the pattern of the Primary F.R.C.S., or an honours degree in physiology, would guarantee special training in the basic subjects. After qualification, a year or eighteen months of resident work, equally divided between the three main branches, followed by a clinical examination ranging over the whole subject of medicine, would ensure a broad general training. After this, each candidate could fulfil the special requirements of the particular College he wished to enter. If this were done, it would ensure clinical teachers with an improved general training, who would be less likely to teach in separate watertight compartments of specialties.

Bristol University Cardiac Research Centre

The autumn issue of the *Bristol Medico-Chirurgical Journal* contains a review by Dr. Carey Coombs of the work of the University Centre of Cardiac Research from 1927 to 1931. Since its inauguration in 1926 by a subcommittee of the Science Committee of the British Medical Association, steady progress has been made with this investigation, and reports have been published from time to time in these columns, the last report appearing in the *Supplement* of July 18th. Dr. Coombs remarks that, since the inquiry is as yet incomplete, only one fact may be legitimately claimed as having been established; but this is one of the highest importance—namely, that the incidence of rheumatic infection of the heart in the city of Bristol is six times as high as that in the surrounding country. The actual figures are: Bristol, with its population of about 400,000, contains 750 children with about disease; while in the surrounding country, with about 1,100,000 inhabitants, there are only 350. Steps are now being taken to find out whether Bristol is singular in this respect, or whether the other great cities of Britain are similarly afflicted. As regards ulcerative endocarditis, the conclusion has been strengthened that there is present an infection of the inner surface of the heart, not of the heart wall itself—an "accidental" implantation of bacteria from the intracardiac blood stream. It follows that this condition is for the most part a terminal infection, indicating a fatal failure of resistance, which may be local or general, or both; it cannot be cured and can only very seldom be arrested. After enumerating

the various lines of research which are being prosecuted at present, Dr. Carey Coombs, envisaging the future, emphasizes the need for rendering the department of medicine in the university more efficient by bringing into existence a university hospital, or a system of hospitals, with the adequate academic departments; the present university centre of cancer research would then be absorbed naturally into the new scheme.

The Shortage of Dentists

Professor C. S. Gibson, F.R.S., of Guy's Hospital, distributed the prizes on October 6th, at the Birmingham University Dental School. The serious shortage of dentists with which the country is likely to be faced was referred to by Mr. Malcolm Knott, who occupied the chair and gave an address. The dental profession, he said, had passed through trying times in the last ten years, but they felt sure the sacrifices that had been made were not in vain when they could say that in future no man could enter dentistry except through a long and intense hospital training. Since the Dentists Act, 1921, a Dental Board had been set up, not only to control and discipline all dentists, but also to make provision for the care of the teeth of the nation. The result had been a great improvement in the status of dentistry and the opening up of new or the extension of existing avenues. If the health of the people was to be properly attended to there must be a considerable addition to the number of those now entering the profession. To make good the losses on the *Register* by death and retirement an average of 625 dental surgeons should be added to the *Register* each year. They were not getting anything like that number—in 1930 the number was only 256. Professor Gibson, in addressing the students, said that dentistry had progressed in every way during the last generation. As science advanced, fresh problems had to be faced and fresh facts had to be explained; and not only had dentistry advanced in knowledge, but also the utility of the profession was becoming far better understood. It must also be remembered that dentistry was looked upon by the past generation as purely a craft; he wished to emphasize the fact that dentistry was not merely a craft, for although workmanship had a great deal to do with it, there was an academic side which allied it to the medical profession. The problems which had to be faced could often only be dealt with by means of research, and he felt that there was a great opening in dentistry for research work. The Dental Board had assisted during the last few years by giving grants, and he hoped that the Birmingham Dental School would in the future be able to grapple with some of these problems and so take a leading part in the solution of difficulties which presented themselves to the dental profession.

Central Midwives Board

At the October meeting of the Central Midwives Board for England and Wales a letter was reported from the Association of Inspectors of Midwives drawing attention to an apparent contradiction between Rule E. 20 and Rule E. 21 (5), inasmuch as Rule E. 20 requires the summoning of medical aid "in all cases of illness of patient or child, or any abnormality," and Rule E. 21 (5) qualifies this by adding "endangering the child's life" and in this connexion pointing out that local supervising authorities have questioned the summoning of medical aid for talipes, which does not endanger the child's life. The association suggested that the substitution of the word "crippling" in Rule E. 21 (5) for "endangering the child's life" would remove the contradiction. A communication was read from the matron of Queen Charlotte's Hospital enclosing a letter she had received from Mr. A. W. Bourne, senior obstetric surgeon to the hospital. He stated that after discussion and consultation with the hospital bacteriologist, the medical staff had decided to abolish the use of antiseptics for swabbing the vulva during the lying-in period in normal cases. Also, that apart from being of little or no value in the prevention of infection, the continued use of antiseptics caused soreness and irritation, which might actually favour the development of the septic condition of the skin. The Board decided to inform the matron of Queen Charlotte's that, whilst having no desire to prescribe the technique at the hospital, it had to be borne in mind that the hospital was an institution at which the training of pupil midwives was approved, and that, whatever technique was employed there, the pupil midwives must receive adequate instruction in the Rules of the Board regulating the practice of midwives, including, of course, Rule E. 8, to which they had to conform in practising domiciliary midwifery. Approval as lecturer was granted to Dr. Eva Joyce Newton, Clapham Maternity Hospital, and to Dr. Charles David Read, Maternity Nursing Association. It was agreed that one of the members of the Board be invited to inspect the examination at Leeds, Manchester, and Newcastle in November or February next.

Correspondence

"WHAT IS LIFE?"

SIR,—Perhaps you will allow me to make a few remarks on your article on this subject in the *British Medical Journal* of October 10th, as the writer of it has partly misunderstood my own contentions, to which the article mainly refers. It is not as a philosopher, but as a physiologist, that in my recently published book I criticized the mechanistic theory of life. Philosophy only comes into the argument in my defence of biology against the intrusion of what seems to me bad philosophy, which has driven physiologists into vain attempts to interpret life on either mechanistic or vitalistic lines.

The argument of the book is not that life is "matter in a superphysical state" (to quote the article), only to be understood by philosophical reasoning, but that if we apply to a living organism the conception of matter we have thereby made it impossible to interpret scientifically the phenomena we are dealing with, because we are separating in thought what cannot be separated in observation. What we actually observe is that the phenomena of life express the maintenance of a co-ordinated whole, which includes within itself relations to environment, as well as the mutual relationships of details of internal structure and activity. Hence it is vain to approach the study of life under the presupposition that its phenomena can be separated from one another, as when we separate in thought "living matter" from its environment. Our proper working hypothesis is that the observed phenomena are inseparably connected with one another as manifestations of the whole which we call a life; and it seems to me that this, and neither the mechanistic nor the vitalistic theory, is the hypothesis that has actually worked successfully through the whole history of biology. It is always with relations that we are dealing in biology, and in the definition of these relations we often require physical and chemical methods of the utmost delicacy; but it seems to me mere confusion in thought to suppose that their application leads to any separation of the related phenomena.

From the time of Galileo up to the beginning of this century physicists seemed to be aiming successfully at analysing visible and tangible phenomena on mechanistic principles into separable events and processes. But

mechanistic and vitalistic biological theories were a reflection of this aim Now that it seems evident that mechanistic principles cannot ultimately be applied to what has hitherto been called the inorganic world, physicists are beginning to look toward biological ideas for guidance One of the clearest instances of this is the very deliberate statement by Planck (*Nature*, March 18th, 1931) that " the assumption that the orderly course of a process can be represented by an analysis of it into temporal and spatial constituents must be dropped The conception of wholeness must therefore be introduced in physics, as in biology, to make the orderliness of Nature intelligible and capable of formulation " Planck's conception of life and of its difference from mechanism, seems to be the same as my own —I am, etc ,

Oxford Oct 17th J S HALDANE

CHILD PSYCHOLOGY

SIR —In an annotation in the *Journal* of October 10th, on the National Institute of Child Psychology, the statement appears that it has been a common cause of complaint by Continental and American visitors that there is no provision for the study of medical psychology in general, and child psychology in particular, in London I think it unlikely that such complaints are widespread, and in any case believe them to be totally unjustified The course for the D P M at the Maudsley Hospital has existed for about twelve years, and a special part of it in May is available for those who can only spare a month for a post graduate course These courses have been attended by a considerable number of foreign and colonial graduates In addition to the lectures there is also a large variety of other opportunities for instruction in medical psychology and clinical work in the Maudsley Hospital The Tavistock Clinic (Institute of Medical Psychology) has also for years organized courses for medical students and practitioners, which are largely attended I am, furthermore, in a position to state that some of the leading psychiatrists in America regard the courses of instruction for the D P M in London and elsewhere in England as admirable in scope and arrangement, and as models which might be followed in their own country

As regards the situation in child psychology, there are, in addition to the National Institute of Child Psychology, at least four highly organized and fully staffed clinics in London—namely, the London Child Guidance Clinic, the Child Clinic at the Maudsley, the Tavistock Clinic, and the Jewish Clinic, each of which has been in existence for several years and has treated a great number of maladjusted children At the Child Guidance Clinic, fellowships are open to suitably qualified medical practitioners and also to psychologists At Guy's and other general hospitals there are psychological clinics for children in which much valuable therapeutic and teaching work is being carried out An intensive course of instruction is given by Dr Moodie at the Child Guidance Clinic , at the Maudsley there is a series of lectures on the nervous and difficult child as part of the D P M course, and conferences and clinical instruction are open to social workers and medical men throughout the year , and there are also similar arrangements at the Tavistock Clinic

It would be most regrettable if the impression were created at home and abroad that the behaviour disorders of childhood were neglected by the medical profession in this country Fortunately, this cannot be said to be the case On the contrary, there is abundant evidence to show that both in London and in many provincial centres this branch of psychological medicine is receiving increasing attention —I am, etc ,

Virginia Water, Surrey, Oct 17th H DEVINE

INFECTION BY ANAEROBIC STREPTOCOCCI IN PUERPERAL FEVER

SIR,—In July, 1930,[1] I reported in this *Journal* the culture of strictly anaerobic streptococci from the blood of seventeen cases of puerperal fever—all these cases having been met with in the previous two years As this result was at variance with the experience of other bacteriologists in this country who have investigated the disease—and, indeed, with my own earlier experience also —I discussed whether perhaps the operations of chance had been chiefly responsible for my meeting with so many cases of an unusual type, or whether, at Queen Charlotte's Hospital, where I had encountered most of the cases, there had been an epidemic spread of these infections Reasons were given for rejecting both these hypotheses as unlikely, and I was driven to the conclusion that such cases are really of fairly common occurrence, and that I, in common with other bacteriologists, had often missed them by the employment of unsuitable blood culture methods During the fifteen months since that conclusion was printed I have had the opportunity of investigating, along with my colleagues Dr R M Fry Dr R Hare, and Dr Elizabeth Cooper, a further series of some 220 cases of puerperal fever These were chiefly cases received in the new Isolation Hospital at Queen Charlotte's Hospital at Hammersmith, which was opened in September, 1930—that is, cases derived from the maternity service of Queen Charlotte's Hospital itself and a rather larger number which had been delivered at home or in other hospitals anywhere in the London area or Home Counties

It is of interest to compare the findings obtained in this series of cases with my previous experience Of the 220 cases, 12 have given a culture of strictly anaerobic streptococci from the blood, usually on more than one occasion In only one case was there associated infection by haemolytic streptococci—the anaerobic variety being cultivated alone from the first blood culture, both varieties from the second and third Four of the 12 cases died, and 8 recovered , 7 of them had been delivered at Queen Charlotte's, and 5 elsewhere

The obstetric history of these cases confirms my earlier impression that infections by anaerobic streptococci are particularly prone to follow upon internal manipulation and an exhausting labour In 9 of the 12 cases under consideration such manipulations had been carried out, either for version, or high forceps delivery, or perforation, or for manual removal of an adherent placenta (3 cases) Only one of the 12 had had a normal labour without undue haemorrhage

We are still unable to say exactly what proportion of the cases admitted to the isolation block are infected by these organisms In about 40 per cent of them material from the cervix uteri yields a culture of anaerobic streptococci, and very frequently they are predominant It is, however, quite possible that in some of the cases these streptococci are present merely as saprophytes, and are not really infecting the living tissues Later on, we hope to get evidence on this point by means of tests for antibodies in the patients' bloods Meanwhile, our impression is that these infections are at least as numerous, although happily not so fatal, as those caused by haemolytic streptococci

The source of these infections is being investigated by Miss Cooper in this laboratory It is highly probable in view of the findings of Rosowsky[2] and other workers that they are true autogenous infections by organisms present in the genital tract before labour, and that these only become infective when the discharges have become " corrupted " by suppuration —I am, etc ,

RHEUMATOID ARTHRITIS

Sir,—"Crippled" (*Journal*, October 3rd, p. 630), though rightly pointing out the futility of dealing with focal sepsis to the exclusion of all else, is in error when she writes that the sex incidence has been but little stressed. Spender, over thirty years ago, laid great emphasis on this feature, and his observations have been confirmed again and again by subsequent writers. For some ten years or so it is true that the constitutional and diathetic abnormalities of the rheumatoid patient were almost forgotten as the result of the baneful influence of the school of focal sepsis and its adherent bacteriologists. All credit is due to Llewellyn, who, during this phase, constantly insisted on the necessity of regarding the patient as a whole, rather than as one composed of teeth, tonsils, and joints. The succession of dismal failures, coupled with the fact that the majority of true rheumatoid arthritics have no demonstrable focus of infection, has at last stemmed the tide of harmful surgical intervention against which some of us have been struggling for years.

Dr. Poynton's characteristically undogmatic and balanced reply to "Crippled" (October 10th, p. 678) indicates that, although he thinks that some form of microbial activity is necessary for the ultimate outbreak of arthritis, he yet believes that sensitization plays an important part in the production of the disease. There are many such indications in modern literature that opinion is coming to regard the joint manifestations of atrophic arthritis as allergic in nature, and therefore closely related to certain metabolic abnormalities generally accepted as belonging to the allergic group. The fleeting character of the initial joint swellings lends support to the view, and the ultimate pathological changes can undoubtedly be produced by vasomotor disturbances in the absence of a microbial agent. Careful desensitization with any form of protein will, in the early stages of an allergic disease, tend to produce benefit, or even cure. Probably this accounts for Dr. Warren Crowe's happy experiences. It would be interesting to know his precise definition of early uncomplicated cases of rheumatoid arthritis. That he has not had a single failure in their treatment with stock vaccines fills one with hope and amazement.

Our knowledge of rheumatoid arthritis has advanced over that of Kent Spender but little, because we have been side-tracked by insistence on infection as the principal etiological factor. Our additional knowledge is that all true cases of active rheumatoid arthritis exhibit a raised basal metabolic rate, considerably diminished sugar tolerance (some of the curves being exactly similar to those of early diabetes mellitis), and an output of urinary proteose (Oriel), which is capable of causing a flare-up of joint manifestations if introduced subcutaneously even in infinitesimal quantities. The significance of these changes is probably profound, but we must be constantly on our guard against accepting any one or other of them as being necessarily etiologically related to the disease, rather than as further manifestations of an all-embracing malady.

"Putting the cart before the horse" has produced edentulous patients whose oral disease was merely the result of constitutional changes. If we can prevent-untempered enthusiasm from making the same mistake in relation to signs suggestive of allergy we may look forward to some degree of real progress.—I am, etc.,

London, W.1, Oct. 12th. A. H. Douthwaite.

Sir,—It is with the utmost diffidence that I venture again into circles where, I am keenly conscious, I do not belong; but Dr. Poynton's letter has roused a desire to make a further observation.

Taking the disease as a whole, through its entire range from the elderly person to the child, there are two striking characteristics. The first is the great variety of causes, or at any rate of predisposing conditions, which give rise to approximately the same symptoms. One might instance such very diverse factors as influenza, exposure to damp or cold, mental worry or depression, dental and tonsillar infection, over-eating, and childbirth. The second characteristic is that no two cases seem to be alike. The end of the unchecked disease for all is crippledom, but the onset, progress, and reaction to treatment in each case is different. I have been wondering whether these two facts do not both point in the same direction, as indications that the disease is not infective but functional. If it were directly due to a primary infection would one not expect it to run a more regular course? And how can one reconcile this theory with the large number of predisposing conditions? I cannot agree with Dr. Poynton that it is a case of anything that "may just turn the balance against a sensitized patient," because in view of the profound disturbance to the organism as a whole, and the prolonged nature of the illness, it seems to me that something very fundamental must have gone wrong. I should have thought it far more probable that the root of the trouble lay in some functional defect, such as a deficiency of some gland secretion. This would account more easily for the variety of predisposing conditions, as various factors might affect the working of a gland, and thus produce the symptoms; even those cases apparently due to a toxic infection might have been caused by the toxin acting, not directly upon the tissues, but upon a gland. And this theory also leaves a margin for idiosyncrasy in the individual, which would account for the lack of uniformity in the development of the disease. The results of the interesting experiments in blood transfusion recently reported by Dr. W. S. C. Copeman also seem to bear out the idea; and if the disease is really of something the same nature as diabetes, it is the more understandable that it should be so much more serious in youth than in maturity.

A further indication which points the same way is that cases are known of cure by "mental healing." Such cases may be rare, but I, in my peculiar position, have heard of at least two which there seems no reason to doubt. These cases could only have improved if the cause of the trouble was controllable by the subconscious—that is, if it was functional. I put the suggestion forward tentatively, but I think those of your readers who may have studied the work of the late M. Coué will allow the validity of the argument. From these considerations, and from the preponderance of women among rheumatoid patients, it might be thought worth while to keep special observation upon the sex organs in such patients.—I am, etc.,

"Crippled."

October 13th.

JAW TRACTION IN BREECH LABOUR

Sir,—I regret that it was impossible for me to make an earlier protest against the method of jaw traction as described by Dr. Bourne at the end of his paper on "The management of breech labour" (*British Medical Journal*, August 29th). In my opinion it is a bad practice to slip the finger into the mouth and pull on the lower jaw. The finger-tips should be slipped over the upper jaw to the nasal pits, and the pull made on the head itself. It is evident that in this position any pressure that can be exerted is at a greater mechanical advantage, and it cannot tear the mouth.—I am, etc.,

R. C. Buist.

Dundee, Oct. 19th.

BREECH DELIVERY

SIR,—The recent correspondence in the *Journal* on this subject is interesting. As a result of a period of twenty-one years in general practice, the salient fact which has impressed itself upon my mind is the length of time which can be taken, with impunity, in delivering the after-coming head. At first the fear of asphyxia made one hurry, with the result that the child sustained injuries to head and limbs. On three fairly recent occasions the nurse has made a remark to me to this effect: "You took more than five minutes over the head; I was sure you were going to lose the baby." Delivery, of course, must be as quick as possible, but my impression is that there is not so much need for hurry as one is led to believe.

I am not convinced yet that the child can inhale liquor amnii while its head is in the pelvis. As to mortality, my deaths have as yet only occurred in those cases which have been deliberately changed into breech presentations.—I am, etc.,

Church Stretton, Salop, Oct. 6th. H. GOOCH, M.B.Lond.

SIR,—In the recent very interesting discussion on breech labour in the *Journal*, has there not been a slight tendency to over-emphasize the importance of the technique of the actual delivery, and to minimize the fact that most breech labours are preventable? Few will deny that the best of all treatments for breech cases is not to have any. A certain residuum indeed there will always be—surprise confinements, versions performed deliberately for obstetrical reasons (a gradually diminishing group), failed external versions, and errors in ante-natal diagnosis. But the fact remains that the vast majority of breech labours are preventable by a proper ante-natal vigilance. Our attitude, then, should be less one of complacency at a difficult breech case brought to a successful end by our dexterity, than one of a chastened humility that there should have been any call for a display of our prowess. It is good to win a cause, but it is better still to win it without a fight.

There are only two kinds of breech delivery: the easy and the difficult. And the important thing is that (except in multiparae with small babies and capacious passages) it is usually quite impossible to tell before labour into which class a given case will fall. The child may come tumbling into the bed unaided, or it may present the torso of a Hercules and the head of a philosopher, and its delivery reduce the unfortunate attendant to a state of nervous and physical prostration. The easy cases can be delivered successfully by any sensible method, but the difficult cases cannot be made easy by any technique whatever. They are inherently difficult, notwithstanding comforting counsel to "keep cool and all should be well." However coolly one may start a difficult case, one is apt to finish very hot indeed. If Mr. Alec Bourne finds the bringing down of extended arms "a most difficult manœuvre," it will probably be equally difficult for most other people. Let us then determine to reduce the number of our breech cases to a minimum, and to approach that minimum with a full consciousness of the hazards involved for mother and child.

Lastly, a stillborn child and a mother with a complete rupture of the perineum is even yet a distressingly common combination. While we have but a limited control over the welfare of the child, the integrity of the rectum is so completely in our power that this minor catastrophe of breech delivery should be almost unknown. A snip with scissors on each side of the vagina at the back part (a simple thing spoiled by a cumbersome name—episiotomy), and the rectum is safe from the most determined efforts to bring down extended arms. The snips are easily sutured. They heal well, and if they do not it is of little consequence. Let them always be done in primiparae. They will be done unnecessarily sometimes, but better ten unnecessary episiotomies than one torn rectum—I am, etc.,

Wisbech, Oct. 13th. A. J. HAWES.

RESUSCITATION OF THE NEWBORN

SIR,—In a paper in your issue of October 17th on the treatment of pneumonia by CO_2 inhalation, Professor Yandell Henderson makes the statement that I have adopted the American methods of resuscitation of the newborn by CO_2 inhalations and refraining from swinging and dipping the infants in cold water, etc.

I should be glad to know when these methods were begun in American maternity hospitals, and what literature is available on the subject. My investigations on the loss of heat and shock in the newborn date from 1924, and were published in the *Proceedings of the Royal Society of Medicine* in 1925 (vol. xviii). Further investigations on the treatment of asphyxia by inhalations of CO_2 and oxygen were published in the *Lancet*, August, 1927, and the *Practitioner*, June, 1931. I know of no literature published on this subject previous to my earlier papers. In a tour of the chief American maternity hospitals last year I did not find anywhere that all forms of artificial respiration had been abandoned, and that CO_2 and O_2 was used as a substitute.

I write this letter partly in defence of British research and partly because my methods of treatment of the newborn were very much criticized. Now time has proved their value.—I am, etc.,

London, W.C.1, Oct. 20th. A. LOUISE MCILROY.

DIPHTHERIA CARRIERS

SIR,—In the *Journal* of October 10th, Dr. George Chesney suggests that the nasal carriers described by me ought to have been labelled "nasal diphtheria," and, as such, effectively isolated. In support of this contention he quotes the definition of a carrier given in the Medical Research Council's publication on diphtheria. I would refer him to the context of that definition, where I read: "Thus difficulty may be experienced in deciding when a case is a carrier or a very mild case of diphtheria. The distinction is artificial" (p. 334). Thus I have included as carriers those patients who harboured diphtheria bacilli in the nose and yet exhibited neither membranous inflammation nor toxaemic symptoms. This attitude is readily supported by Goodall, who states, "A large proportion of carriers present some pathological condition such as rhinitis" (*Infectious Diseases*, p. 218). In this connexion I would also refer to the report on the diphtheria carrier clinic at Guy's Hospital (L. W. and R. J. Cann, 1927).

A number of nasal infections in Burton-on-Trent were, in fact, called nasal diphtheria, and isolated in hospital. These were characterized by actual membrane formation, other severe nasal lesions, or else by constitutional symptoms. The cases which attended for treatment at the clinic as "carriers" were quite free from constitutional disturbance, and the local nasal lesions were slight. As hospital isolation is the only effective isolation in an industrial community, and as the available accommodation was urgently required for the treatment of faucial diphtheria, Dr. Chesney will quite readily understand why the treatment of the cases in dispute had to be carried out elsewhere. Simple exclusion from school was not enough, and the daily supervision and treatment at the school clinic probably rendered them as harmless to the

community as hospital isolation would have done. Here I must remind Dr. Chesney that the policy of effective isolation has signally failed to control diphtheria, and that the modern hospital treatment of diphtheria has for its main object the prevention of mortality. I do not therefore favour, as a rule, the removal to hospital of cases of mild nasal infection with diphtheria bacilli, for the only good effect would be to dilute the percentage mortality rates. Dr. Chesney will not accuse me of despising these nasal conditions if I agree with him as to their tendency to form foci of infection in the community. It is, however, difficult to discover them until after the damage has been done. A few may be detected at random by medical inspection of school children, but the majority will escape, and, as in my own experience, many precisely similar lesions will be found which will never yield a positive swab.

Attempts to control diphtheria by isolation of carriers (or mild cases) have failed, and the attainment of a Schick-negative community will only be the fruit of tremendous labour. So diphtheria must remain in our midst, but the elimination of diphtheria mortality should not be an impossible ideal, since we are all agreed on the efficacy of prompt diagnosis and treatment in faucial and laryngeal diphtheria.—I am, etc.,

Public Health Department, Ayr, Oct. 12th. JAMES GRANT, M.B., Ch.B., D.P.H.

COMMON INJURIES OF THE KNEE-JOINT

SIR,—In a leading article in the *Journal* of October 10th the question is raised of whether joints from which one or both menisci have been removed are more or less liable to arthritis than their fellows, twenty years later. This is a question which would have been dealt with in the opening paper on "Treatment of common injuries of the knee-joint" had time permitted. The cases which one sees with osteo-arthritis of the knee are so often those giving a history of cartilage injury in early life, for which no operation was advised, that it seems reasonable to suppose that this has resulted from or been aggravated by repeated trauma to the joint. Such experience as I have is very definitely that in selected cases of recurrent lesions of the knee-joint, only surgical treatment can restore normal function, and that operation is also the safest insurance against later arthritis.—I am, etc.,

Birmingham, Oct. 17th. NAUGHTON DUNN.

UROBILINOGEN

SIR,—During the past few weeks I have been surprised to find the extreme prevalence of a positive reaction for *urobilinogen* in the urines of many people with disordered health. For years past, in the routine examination of urines, I interpreted the obtaining of a negative reaction for urobilin as indicative of no great hepatic disorder. From symptoms and other clues, however, I felt I should have got a positive reaction.

Although aware of Ehrlich's benzaldehyde reaction for urobilinogen, I was under the impression that the tests were equivalent. I was surprised, therefore, some three weeks ago, to find in the urine of a patient suffering from indefinite abdominal signs a strongly positive urobilinogen reaction when all other tests were negative. Since then I have been testing out in all kinds of illnesses, and find a positive—and sometimes the only positive one—in many cases taken recently ill. The reaction of most of the urines was alkaline, and acetone was present in the majority. My greatest surprise was to find it positive in the case of loss of vision in a man, aged 60, who came for glasses, where the urine was clear like water, with a specific gravity of 1001. He had also arterio-sclerosis and high blood pressure. Other eye cases seen recently—catarrhal conjunctivitis in one eye with herpetic eruption on the lips in a young patient with myopia—gave a very strong positive reaction; and in still another, with inflammation of the uveal tract, a positive reaction was also obtained. In colds, catarrhs, skin eruptions of the erythema multiforme type and dermatitis herpetiformis, of which I have seen several in the past weeks, and many other seasonal complaints, the reaction was frequently present.

This points to damaged hepatic cells[1] which are unable to deal with the urobilinogen which is returned from the colon. Its significance is that of marked putrefaction in the lower bowel.[2] The further significance is that in cases which seem to have no evidence of an etiological factor—obscure eye inflammations, obscure skin disorders, neurological cases, cardio-vascular disorders—the finding of this test positive is indicative not only of injured hepatic cells, but also of an unsuspected bowel toxaemia. Influenza and measles have been recognized for a long time as leaving a residuum of intestinal auto-intoxication which makes convalescence so tardy.

What if it should be found that such reaction is positive prior to the onset of such illnesses? May it not stand in relation to these disorders at least as a partial etiological factor? Whether the frequency with which I have found it positive in the past few weeks is associated with the season, time will show. But that such a condition can go on silently and hidden may indicate the link in a chain of evidence, which has been accumulating, of the great part bowel poisons play in various diseases.

Tests of the urines for bile salts (Hays) were sometimes very faintly positive. Van den Bergh's tests to find the form of bilirubin present have not been done—that is, direct, indirect, and biphasic. It is said[3] that it takes a considerable time before the injury of the hepatic cells and the accumulation of sufficient bilirubin in the blood give a positive reaction in the urine. The renal threshold for bilirubin is raised in haemolytic jaundice.

That the above interpretation may not be the true one I am fully aware. Thus bilirubin, from destruction of blood corpuscles by haemolysins, can be formed in other parts of the system besides the liver; and the production of bile can be increased even by 100 per cent. from other materials than haemoglobin by simply feeding with large carbohydrate diet.[4] However, I regard the interpretation as worthy of consideration. In about a dozen of the cases recently seen giving a positive Ehrlich reaction, Mutch's tyramine reaction was done to see if there was any abnormal bacterial action (carboxylase) associated with the presence of a positive Ehrlich reaction. Several gave positive reactions; but as sometimes it was not a pure ethereal extract which was obtained I could not rely on the results.—I am, etc.,

Darlington, Oct. 8th. R. CHALMERS, M.D., F.R.C.S.Ed.

THE LARYNGOSCOPE IN MEDICINE

SIR,—May I be allowed to point out a source of misunderstanding in the abridged report of my presidential address on the above subject, which you have done me the honour of publishing in your current issue? At page 703, paragraph 4, line 7, the "intrinsic cause" to which reference had been made was primary carcinoma of a vocal cord. If this be not mentioned, the sentence below commencing with "What a tragedy . . ." must be very

[1] Beaumont and Dodds: *Recent Advances in Medicine.*
[2] Bassler: *Diseases of the Alimentary Tract.*
[3] Beaumont and Dodds: Loc. cit.
[4] MacLeod's *Physiology.*

ambiguous. In regard to the second paragraph on page 704, the scriptural quotation I had in mind was from St. Mark, iv, 22: "For there is nothing hid which shall not be manifested."—I am, etc.,

London, W., Oct. 17th. HERBERT TILLEY, F.R.C.S.

FATS AND PEPTIC ULCER

SIR,—I think a really good negative is worth a score of inconclusive positives. I had a gastro-jejunostomy in 1918 for pyloric obstruction due to healed duodenal ulcer. I had contracted this trouble at the beginning of the war, and it had accompanied the whole of my military service. From earliest recollection I have had a fat intolerance. As a child I would never eat fat, and as an adult I avoided the least trace. One or twice I forced myself to eat fat, but the result was intense discomfort followed by vomiting. Milk, if drunk in quantity, caused very pale stools loaded with fat. Even now I have to take the greatest care in avoiding anything that is at all greasy. The only exception is butter; I can take a fair quantity of that.—I am, etc.,

Manchester, Oct. 15th. M.D.LOND.

HUNGER PAIN AND PRESERVATIVES

SIR,—That butter does not now contain preservatives I am pleased to know, and the blame which I attached to that food is to be attributed to certain proprietary articles that were banished at the same time. Not knowing what did contain preservatives I excluded everything which was not fresh in the literal sense of the word. With this dietary, hunger pains have gone, but they can again be induced by eating food with preservatives. Several years have gone by since I discovered my sensitiveness to adulterated food, and what perhaps is singular is that, with the passage of time, the sensitiveness has not abated.

Besides ourselves America is partial to preserved foods, whereas France depends largely on local produce, and if preservatives are a factor in the provoking of duodenal ulcers these disorders should be less prevalent with the French. If the requisite statistics are available they would be of value in assessing the influence preservatives have with those gastric troubles that are the bane of middle age.—I am, etc.,

London, W., Oct. 9th. JAMES FORREST.

THE TERM "CONGENITAL"

SIR,—In reply to Dr. Melgrave (October 10th, p. 681), I cannot quite appreciate his difficulty with regard to the use of the term "congenital." The word means "born with," and may quite properly be used as an adjective for syphilis acquired during ante-natal life, because the infant is born either with the disease or with the spirochaete in its body. It is a term which has nothing to do with hereditary transmission, and can no more be confused with "hereditary" or "inherited" than the term "ante-natal." As regards the term "connatal," to express infection acquired during the process of birth, I agree with Dr. Eric Pritchard that the word "intranatal" is one which, for several reasons, is more suitable.—I am, etc.,

London, W.1, Oct. 16th. W. M. FELDMAN.

SYNDROMES OF THE JUGULAR FOSSA

SIR,—I have just returned from a short holiday to read with interest Mr. N. Asherson's letter in the *Journal* of October 10th (p. 680), and can say with certainty that the tumour was not of tuberculous origin, nor did the petrous portion of the left temporal bone show any evidence of destruction. Unfortunately, we could not obtain permission for a more complete post-mortem examination. Our aim in writing the note published in the *Journal* of September 26th was to stress the difficulty in the diagnosis between a penetrating squamous carcinoma and a chordoma.—I am, etc.,

E. T. RUSTON, M.B., Ch.B.

Pathological Department, Royal Surrey County Hospital, Guildford, Oct. 15th.

PHYSICAL EDUCATION IN SCHOOLS

SIR,—In your report in the *Journal* of October 10th of Lord Dawson's address at Epsom College, it was particularly pleasing to read Lord Dawson's admirable remarks on the great value of properly conceived physical education. Those of us who ended our school days before the war, and suffered much at the hands of the time-expired sergeant of marines, with his squad drill and German gymnastics, may little realize the great developments that have taken place, largely as the result of the stimulus of the Board of Education, in the development of physical education in schools. A full physical examination often reveals errors of posture and physical defects, which will disappear during a boy's school life if properly cared for in a well-controlled course of physical training.

I have for the last few years been connected with the large day school at the Polytechnic in Regent Street, W., and have been enabled to see the good results obtained and borne out by records. I have asked the director of education at the Polytechnic to allow any medical practitioner who is interested to call in and see both boys and girls at work in either of the gymnasiums in the main building or the extension off Great Portland Street. Major Worswick is very pleased to extend this invitation, as the gymnasiums are in almost constant use by the schools between 10 a.m. and 4 p.m. each day.—I am, etc.,

London, W.1, Oct. 13th. T. PEARSE WILLIAMS.

BRITISH DOCTORS AND BRITISH HEALTH RESORTS

SIR,—In his very timely letter headed "A plea for British spas," published in the *Journal* of October 17th, "Medical Superintendent" writes:

> "The attractions of foreign spas and winter resorts are depicted so skilfully and alluringly that many are better known than those in this country, and the English doctor is often at a loss to know where similar benefits at home may be readily obtained, and with equal advantage to his patient. It is surely high time that some independent and influential medical body should undertake this task, investigate our resources, and be prepared to advise English medical men who need help in such matters."

This was one of the purposes for which the Committee for the Study of Medical Hydrology in Great Britain was formed, and as a national appeal has been made to British subjects not to go abroad without real need, the following brief account of the origin and work of the committee may be of present interest.

Partly owing to the already crowded state of the medical curriculum, and for a number of other reasons which need not be stated here, the subjects of medical hydrology, climatology, and physiotherapy in general are given very little attention in the medical schools in this country, and are certainly not systematically taught as they are in most Continental medical schools. To fill this gap a committee, consisting of medical men from practically all the British spas and from London, was formed, and they in turn drew up a panel of lecturers, all of whom have expert knowledge of climatology and spa treatment. These lecturers are available to give addresses, illustrated by film and lantern slides, to any medical school or medical society. It should be clearly understood that the

function of this committee is education, and not advertisement. The panel includes lecturers from London as well as from the spas; the list is sent to medical societies on application, and they have free choice of lecturer. The lectures deal with the nature of, and indications for, spa treatment, as well as the grounds for selection of a particular spa and the steps to be taken by the practitioner who wishes to send a case for treatment.

It is hoped that the scope of the committee's work will be considerably extended by the decision of the British Spas Federation at its last meeting to offer special facilities to parties of medical men, and of fourth and fifth year medical students, to visit certain of the British spas. For such parties a day's programme will be arranged, of which the principal features will be a conducted tour round the spa bathing establishments, with a lecture-demonstration on the general principles of spa treatment and on the types of cases suitable for treatment at the various spas.

"Medical Superintendent" suggested that the British Medical Association might undertake to investigate our resources for spa treatment and to advise English medical men who need help in such matters. I am quite sure that any assistance the Association can give in the common interests of patients, medical profession, and health resorts alike, either by way of investigation or publicity, would be very welcome. There is need for such help, particularly in the case of health resorts other than the spas, which are not represented by any organization, though it may be noted that very useful information is given in the section on "Spas and marine health resorts of Great Britain, Ireland, and New Zealand" in the *Medical Directory*.

I shall be glad to forward full particulars concerning the above-mentioned lectures and the facilities offered for visits to the spas to the secretaries of any Branches or Divisions of the British Medical Association, or of any other medical societies.—I am, etc.,

GEOFFREY HOLMES,
Honorary Secretary, Committee for the Study of Medical Hydrology in Great Britain.

11, Ripon Road, Harrogate, Oct. 19th.

BRITISH GOODS FOR HOSPITALS

SIR,—Might I ask members of the medical profession to do their best to carry out the request of the Prime Minister to buy British goods? For years I have tried to impress upon the staffs of hospitals with which I am connected the desirability of buying British goods, especially catgut, rubber gloves, drugs, and appliances. At the present time these are bought largely from foreign sources, possibly through carelessness. It is true that sometimes foreign articles are cheaper than the home products, but that is because the trade of their own country is protected, and the traders have acquired half (or more than half) of our trade, and can therefore manufacture in larger quantities. If we individually try to increase our markets at home, then we will be able to manufacture in larger quantities, and prices will come down.

It may be argued that charitable institutions should buy in the cheapest markets, and that they should take no share in party politics; but this is not a question of party politics, it is one of national expediency; and charity, even in charitable institutions, begins at home. Any money going abroad at the present time increases the trade balance against us, and we, as members, can each do our part in urging hospital secretaries, stewards, and the matrons of the smaller hospitals to give the work to our own people.—I am, etc.,

London, W.1, Oct. 16th. DUNCAN C. L. FITZWILLIAMS.

VACCINATION AND ECONOMY

SIR,—Among the many suggestions that have been made to save public money in these hard times there is one which I have not yet seen put forward, and I therefore venture to do so. I think that a considerable sum might be saved by reducing the expenditure on vaccination against small-pox. Not for one moment do I doubt the efficacy of Jennerian vaccination against this disease, but the law enforcing compulsory vaccination has been almost a dead letter for many years, and very few up to the present are a penny the worse. There is indeed plenty of small-pox in this country, but it is of the mildest possible variety. We have been told that our endemic small-pox may at any time alter its character and become virulent, but so far, although rife for a number of years, this has not happened. All the virulent cases of the disease which have occurred during the last twenty years have been imported from abroad, and the sporadic outbreaks resulting from them have been easily controlled by systematic vaccination and isolation of contacts. As long as small-pox is a notifiable disease—and a notifiable disease it must remain—virulent cases imported in the future will be amenable to the same measures. It is, however, a waste of public money to provide vaccination at the public expense for all and sundry. In my opinion public vaccination should be restricted to: (1) contacts with a case of virulent type; (2) members of the various public services (Navy, Army, etc.), who are likely to be sent abroad. If vaccination by public vaccinators were restricted to these categories the amount of money expended by the State could be reduced to less than one-tenth of what it costs at present.—I am, etc.,

H. HALDIN-DAVIS, M.D., F.R.C.P.

London, W.1, Oct. 19th.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on October 15th the following medical degrees were conferred:

D.M.—R. M. Humphreys.
B.M.—M. W. C. Oldfield, J. H. Hunt, N. L. Rushby.

UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated:

ACADEMIC DIPLOMA IN PUBLIC HEALTH.—Katherine Barnett, R. E. Barrett, H. L. W. Beach, Sarah Boyle, E. Cochrane, May P. Cowell, H. A. Crouch, N. J. England, D. W. G. Faris, Marguerite M. Fenn, H. S. Gear, J. E. Howard, I. J. Jones, G. C. Kelly, T. C. Lonie, Hazel Machado, G. R. Marcano, Hilta I. C. Pfister, S. M. Rafi, Dorothy M. Rees, Florence M. Rhodes, J. T. N. Roe, A. P. Ross, B. M. Roy, C. R. Selous-Jones, S. P. Srivastava, A. T. Till, Sarah M. F. Walmsley, W. J. Webster.

UNIVERSITY OF SHEFFIELD

At the congregation held on October 14th the following medical degrees were conferred:

M.B. AND CH.B.—J. E. Edson.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

At the Autumn Commencements of Michaelmas term, held on October 13th, the following degrees in the Faculty of Medicine were conferred:

M.D.—G. M. Irvine, H. B. van der Merwe.
M.B., B.Ch., B.A.O.—M. E. Kirwan.

UNIVERSITY OF GLASGOW

At the graduation ceremony held in the Bute Hall on October 17th the following degrees were conferred by Principal R. S. Rait:

M.D.—*J. Fine, *D. R. Hamilton, W. D. Allan, T. J. Steven, J. Stirling.

M.B., Ch.B.—*R. J. Lumsden, *Anne C. Aitkenhead, *W. S. Bell, *W. A. Roxburgh, *A. T. Elder, *A. Lyall, Eleanor Badenach, P. Binnington, N. V. Birrell, M. D. Black, J. C. Blair, A. M.

* With commendation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

quarterly council meeting was held on October 15th, when ie president, Lord Moynihan, was in the chair.

Mr Ronald Yates Stevenson was introduced, and signed the oll of Macloghlin Scholars. Diplomas of membership were anted to P S Bassalyi, H N. Gregg, G S Malik, Sosa attnew, A Shafi, and G. Steane.

Sir Percy Sargent and Mr. Wilfrid Trotter were re-elected embers of the executive committee of the Imperial Cancer esearch Fund

It was reported that ten out of twenty candidates were iccessful at the primary examination for the Fellowship, hich was held at Melbourne in August. It was also reported iat ten candidates had applied for admission to the primary amination for the Fellowship to be held at Toronto on ctober 20th and following days

Annual Meeting

The annual meeting of the Fellows and Members will take ace at the College, Lincoln's Inn Fields, W.C , on Thursday, ovember 19th, at 3 p m. Copies of the annual report to land before the meeting can be obtained on application the secretary of the College. Motions to be brought forward the meeting must be received by the secretary not later an November 9th.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

a meeting of the College, held on October 14th, Sir Norman alker president, in the chair, it was resolved that, in view the national situation, the ceremonies in connexion with e celebration of the 250th anniversary of the foundation the College be postponed to a future date to be determined the College.

CONJOINT BOARD IN SCOTLAND

e following candidates have been approved at the examina- as indicated

FINAL PROFESSIONAL.—O Rosset, Jean V Rosset, C Hoole, O E R Chavasatne, W E MacDougall, J I Meikle, R F Hudecek, B Taylor, D K Cowan, J G Thomson, F Ludeni, S E terson, A V Piens, L J Scott, A A McNish, J Jansen, R Gupta, D Tolmie, D Houston, F C John, A J Ritchie, Taylor, E J Ratnavake, A I Sayed, L Lumbinoon, T Innasagam, A P. The Services

DEATHS IN THE SERVICES

rgeon General Thomas Grainger, C.B , Bengal Medical rvice (ret), died at the Bolingbroke Hospital, London, on ptember 21st, aged 68. He was born on December 25th, 62, the son of Mr. Robert Grainger of Dundonald, and was ucated at Queen's College, Belfast, where he took the M.D., th honours, M Ch , and B A.O. of the Royal University of land in 1884 Entering the I M.S. as surgeon on October t, 1885 he became surgeon major after twelve years' service, d six months later got a special promotion to lieutenant-lonel for his services in the Tirah campaign. He attained e rank of colonel on December 3rd, 1909, and that of rgeon general on May 25th, 1914, and retired on April 29th, 18 He served on the North-East Frontier of India in e Sikkim campaign of 1888, and was present at the forcing the Jelapla Pass (medal and clasp), on the North-West ontier in the Hazara campaign of 1891 (clasp) ; and in e Tirah campaign of 1898, when he took part in the tions of Dargai, and of the Sampagha and Arhanga Passes, id the operations in the Bara Valley, was mentioned in spatches in G G.O No. 244 of 1898, receiving the frontier edal with two clasps, and a special promotion to lieutenant-lonel For the next ten years he served in civil employ in engal, where he was for a long time civil surgeon of urshidabad He received the C.B. in June, 1911, a good rvice pension on April 2nd, 1914, and was made honorary rgeon to the King on April 1st, 1915.

Obituary

SIR J. HAWTREY BENSON, M.D., LL.D.

Past President, Royal College of Physicians of Ireland

As briefly announced in our last issue, Sir J. Hawtrey Benson, M.D., F.R.C.P.I., died at his residence in Fitzwilliam Square, Dublin, on October 9th, at the advanced age of 88. He was the second son of Professor Charles Benson, M.D., of 42, Fitzwilliam Square, a former President of the Royal College of Surgeons in Ireland. His mother was a daughter of Mr. Maunsell Andrews of Raheny House, King's County. Concurrently with his Arts course, John Hawtrey Benson studied medicine at the Royal City of Dublin Hospital and at Sir Patrick Dun's Hospital, as well as in the schools of the Royal College of Surgeons and Trinity College, Dublin, taking his M.B. degree at Dublin University in 1865, and proceeding a few years later to the M.D In 1866 he obtained the L.R.C.P.I. diploma, and in 1874 was elected to the Fellowship of the Royal College of Physicians of Ireland.

In 1866 he was appointed honorary assistant physician to the Royal City of Dublin Hospital, and two years later was promoted honorary physician, a position which he held until 1894, when he retired from the active staff and was elected consulting physician to the hospital. For over forty years he held the appointment of medical adviser in Ireland to the Colonial Office, retiring from that office in 1926 In 1910 he was elected President of the Royal College of Physicians of Ireland, and held that office again in 1911. He received the honour of knighthood in March, 1912, and in July of the same year the honorary degree of LL.D. was conferred on him by Dublin University. In 1871 he married Dorothea, daughter of the Rev. Thomas Power, incumbent of Templeree, County Tipperary, and formerly rector of Clashmore, County Waterford, who died in 1923. He had no children.

R. M. MANWARING-WHITE, M.D., F.R.C.S.Ed.

President, Lancashire and Cheshire Branch, British Medical Association

The news of the unexpected death of Dr. Richard Manwaring-White of Northwich, at the age of 52, came as a great shock to the people of Cheshire, and especially to his fellow medical practitioners over a large area, by whom he was held in the highest esteem He was the second son of the Rev. E. R. Manwaring-White, vicar of Mendlesham in Suffolk, and from Pocklington School, York, proceeded to Edinburgh University, taking the M.B., Ch.B. degrees in 1903 He held the appointment of house-surgeon at the David Lewis Northern Hospital at Liverpool under Mr Monsarrat, and the appointment of house-physician under Dr Warrington at Liverpool Children's Hospital He afterwards sailed to China as a ship surgeon, and spent some time in Hong-Kong, where he wrote his thesis for the M.D , which he took in 1906. In the following year he began practice at Northwich, and took his F.R.C.S Ed. in 1914. At the outbreak of the war he volunteered for service, but was refused on three occasions. His senior partner, Dr. Dorman, was accepted,

and Dr. Manwaring-White had to work a very large practice single-handed. Notwithstanding this, he took on more work to release others for service, and, in addition, was surgeon to the British Red Cross hospitals at Winnington and Witton Vicarage, as well as being doctor to the Gadbrook Works, where the employees were manufacturing T.N.T. Later he went to Blackpool as medical officer to the Red Cross Hospital, and subsequently, at the request of Sir Robert Jones, he went to assist at the Orthopaedic Hospital at Alderhey, Liverpool, where he remained until the end of the war. He was surgeon to the Victoria Infirmary, Northwich, and to the Mid-Cheshire Orthopaedic Clinic. He was certifying factory surgeon, surgeon to the Post Office and to the police at Northwich, and held various appointments to industrial undertakings in the neighbourhood, notably to the works at Lostock of the Imperial Chemical Industries.

Here was a man doing the work of two men, yet he found time to attend meetings of all sorts—Annual Representative Meetings, Branch Meetings, Divisional and executive meetings, and meetings of the Cheshire Panel Committee. His death has deprived the Lancashire and Cheshire Branch of its president and the Mid-Cheshire Division of its representative and former chairman. Endowed as he was with but a frail physique, he never spared himself in the interests either of his patients or of his fellow practitioners. To attend even an executive meeting of the Division he would drive his car through long miles of fog. When the Mid-Cheshire Division was asked to send in a name for the presidency of the Branch, with one accord that of Dr. Manwaring-White was sent. In June he delivered his presidential address, which amply testified to the width and to the depth of his medical knowledge. He was accustomed to think matters out for himself, and was not afraid to criticize the action of headquarters whenever he thought it necessary, and he did it in no uncertain manner. He is lost to the Association, just when his influence was being felt by those with whom he came in contact, and in the Mid-Cheshire Division, for which he did so much, there is no one to take and adequately fill his place.

R. D.

THE LATE DR. CHEARNLEY SMITH

Sir Alexander Houston writes: Many Merchistonians must have read with deep sorrow in the *Times* of the death of Dr. W. Chearnley Smith. The school register reads as follows: "Born 4th June, 1865, played in the first fifteen 1881–84, in the first eleven 1881–84; left 1884. Edin. Univ., M.B., C.M., 1890. St. George's Hospital, London. Served in the South African War as Surgeon Captain, 8th Batt. Imperial Yeomanry 1900–1." And now we must write "Finis, October 18th, 1931." Chearnley Smith was a great athlete, and his handsome face and figure and breezy personality made him seem almost like a god to his admiring school-fellows. Those were the days (1881–84) of giants in the "rugger" world of Merchiston—Tom Anderson, Fred Goodhue, the Neilsons, Macmillans, Scotts, and Jones's. Later, Chearnley Smith played "rugger" for Edinburgh University and, I think, for St. George's and the United Hospitals. Only about a year ago Chearnley, still retaining nearly all the beauty of face and figure and vigour of his youth, told the writer that he had only two athletic regrets: one was that he had never been chosen to play for Scotland—and indeed it was always a mystery to his friends that the selectors passed him over—and the second was that he only got *second* prize for throwing the cricket ball, although he threw well over 100 yards. Since Merchiston and University days I saw Chearnley Smith all too seldom, but the bonds of good-fellowship, of reminiscences of Merchiston and Edinburgh University, remained ever green, as will his dear memory. I am not qualified to speak of his professional attainments, but can well imagine that his patients must have thought his mere presence a finer tonic than all the drugs in the *Pharmacopoeia*. His obituary notice says: "It was his special request that there should be no flowers and no mourning," and so Merchistonians will think of Chearnley chiefly when the sun is shining, and when they are watching great athletic contests and games of skill, in all of which he excelled.

We regret to announce the death of Dr. Herbert Annesley Eccles, on October 4th, at the age of 62. He came of a family long connected with medicine. He was a son of the late Dr. W. Soltau Eccles, and only brother of Mr. W. McAdam Eccles, consulting surgeon to St. Bartholomew's Hospital. From University College School he went to St. Bartholomew's in 1886, and obtained the M.R.C.S., L.R.C.P. diplomas and the M.B. degree of the University of London in 1891, proceeding M.D. in 1893. At St. Bartholomew's he was house-physician to Dr. Samuel Gee, and, later, succeeded his father in practice in Upper Norwood. During the war he became an expert in the radiology of jaw injuries, serving as medical officer in charge of the *x*-ray department of the Croydon General Hospital from 1915 to 1923. He was also radiologist to the Norwood Cottage Hospital, and for two years chief assistant in the *x*-ray department of St. Bartholomew's. Dr. Eccles retired in 1924, and went to live at St. Just-in-Roseland, Cornwall; he will be greatly missed by all his numerous friends, and, in particular, in the county he had made his own.

Medical News

Dr. W. Langdon Brown will deliver the inaugural address before the Abernethian Society of St. Bartholomew's Hospital on Tuesday, November 3rd, at 8.30 p.m., in the medical and surgical theatre. His subject is "Dr. Robert Bridges, the poet of evolution."

On Friday, October 30th, at 5.15 p.m., the autumn series of Chadwick public lectures will be inaugurated in the Great Hall of the British Medical Association, by Dr. F. J. McCann, who will lecture on "The prevention of cancer." Sir William J. Collins, chairman of the Chadwick Trustees, will preside. Among other lectures in metropolitan and provincial centres arranged for the autumn and coming spring will be "The outlook on tuberculosis—now and then," by Sir Robert Philip at Gateshead, November 13th, and "Benjamin Ward Richardson—his life and work," by Dr. J. D. Rolleston, at the Medical Society of London on February 18th. Further information may be obtained from the secretary, Mrs. Aubrey Richardson, at the offices of the Trust, 204, Abbey House, Westminster, S.W.

A series of six "Tales of travel and adventure" (illustrated by lantern slides or cinematograph) will be given in aid of King Edward's Hospital Fund for London at the Portland Hall, Regent Street Polytechnic, on Wednesdays, at 5 p.m., from November 4th to December 9th. Tickets may be obtained from the secretary, King Edward's Hospital Fund, 7, Walbrook, E.C.4, or at the doors.

The National Institute of Industrial Psychology has arranged a course of three public lectures, under the Heath Clark Bequest, on recent research into the causes of industrial accidents. They will be delivered by Mr. Eric Farmer, investigator to the Industrial Health Research Board, on Mondays, November 2nd, 9th, and 16th, at 6 p.m., at the Royal Society of Arts, John Street, Adelphi, W.C. Admission free without ticket.

The sixth Austrian Congress Against Alcoholism will be held in Vienna from November 21st to 23rd, when the special subject for discussion will be the treatment of inebriates, particularly the legislation on this subject.

OKMAN'S PARK STATION (L.N.E.R. main line). [illegible] Tavistock Square, W.C.1.

The following lectures, arranged by the Fellowship of edicine and Post Graduate Medical Association, will be ven in the lecture room of the Medical Society of ondon, 11, Chandos Street, W: October 28th, at 4 p m, r R O Moon, "Heart disease" (no fee), October 26th, 5 p m, in connexion with the M R C P. course, Mr L Gimblett, Medical ophthalmology—with special ference to retrobulbar neuritis, infective diseases of the eal tract, and intracranial lesions", October 26th, at 30 p m Dr J W McNee, "Recent work on diseases of the liver", and October 28th, at 8 30 p m, "Recent ork on diseases of the spleen" (fee for each, 10s 6d, vailable at the lecture room) Free post graduate demon- rations will be given as follows October 27th, at 3 p m, r Leonard Findlay at the East London Hospital for hildren Shadwell, and at 6 30 p m, by Mr Gilbert ubb at the Golden Square Throat Hospital, W Courses November are as follows November 2nd to 21st, edicine surgery and gynaecology at the Royal Waterloo ospital (fee £3 3s), November 2nd to 28th, neurology the West End Hospital for Nervous Diseases, Welbeck reet at 5 p m daily (fee £2 2s), this course will only held if a minimum of ten enter, and early application desirable November 2nd to 6th, proctology at Gordon ospital (fee £1 1s), Royal Westminster Ophthalmic ospital, November 9th to 28th (fee £4 4s) Details other courses will be announced later Copies of Pabuses may be obtained from the Fellowship of edicine 1, Wimpole Street, W 1

A quarterly court of the directors of the Society for chef of Widows and Orphans of Medical Men was held 1 October 14th, when Mr V Warren Low, president, s in the chair The deaths of two of the widows was ported One, who had been in receipt of grants since 126, had received £450, her late husband had been a emb r for four years, and paid in subscriptions £8 8s he other had been on the funds since 1922, and had ceived £750 in grants, her late husband was a member r twenty years, and paid in subscriptions £42 Special ants amounting to £107 10s were voted for the sistance of orphans with their education, and £610 was so voted as a Christmas present to the widows and phans to be paid in December Each widow over 75 ears of age is to receive £15, those under 75 £10 and ch orphan £10 The new Legacy Book was shown and reatly admired The book has been illuminated and grossed by Sir Frederick Hallett, and was acknowledged y all who saw it to be most artistic A cordial vote of hanks was passed to Sir Frederick Hallett for the time nd skill he had expended on the work The society is pen to any medical man who, at the time of his election, resident within a twenty mile radius of Charing Cross articulars may be had from the secretary at the offices, Chandos Street, W 1

The first award of the Colyer prize is due to be made the Royal Society of Medicine in July, 1932 This rize was founded in 1926, to commemorate the twenty ve years service of Sir Frank Colyer as honorary curator f the odontological museum The accumulated income f the fund may be used every third year for the purpose f awarding a prize for the best original work in dental cience completed during the previous five years, by a ental surgeon educated at any recognized dental school n Great Britain or Northern Ireland who has not been qualified to practise more than five years at the date of he award Applications from candidates should be sub- nitted to the secretary 1, Wimpole Street, W, not later han March 31st together with a general account of their s arches both completed and in progress

The issue of *Paris Medical* for October 3rd, which is levoted to neurology, contains an account of the Inter national Neurological Congress held from August 31st to September 5th at Bern, in which the British speakers ncluded Sir James Purves Stewart, who dealt with the neurological and psychiatric symptoms of cerebral umours Messrs Hugh Cairns and Stanford Cade, who liscussed the effect of radiotherapy and radium therapy on cerebral tumours, Dr Graham Brown of Cardiff, who lescribed the tonic responses of the mesocephalon, Dr Denny Brown, the role played by the terminations of the afferent nerves on muscular tonus, Dr S A K Wilson, disorders of tonus at different physiological levels, Dr J G Greenfield, the anatomy of acute non suppurative infections of the nervous system, and Dr C P Symonds, the diagnosis and treatment of syndrome following injuries of the head

Mikrokosmos, the monthly journal for applied microscopy, microbiology, and microscopical technique, published at Stuttgart under the editorship of Dr G Stehli, enters on its twenty fifth year with its October issue

At the close of the second International Hospital Congress, held last summer at Vienna, it was decided that an international hospital association should be formed with the object of bringing about an international exchange of opinion and co operation in all problems and fields of hospital work The association is to consist of two classes of members—namely, those consisting of individuals associated with hospitals in one way or another and those representing firms standing in a business relationship to the hospital, such as architects builders merchants, etc The annual subscription for the first group is 5 dollars, and for the second 10 dollars

Brevet Lieut Colonel A B Harris, T D has been appointed a deputy lieutenant of the county of Essex

The buildings of the Medical Faculty at Seville have been almost entirely destroyed by fire, entailing a loss of about two million pesetas

Letters, Notes, and Answers

All communications in regard to editorial matters should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names

Authors desiring REPRINTS should communicate with the Financial Secretary *Medical Journal* Association House, Tavistock Square, W C 1 on receipt of proof

All communications with reference to ADVERTISEMENTS as well as orders for reprints of articles should be addressed to the Financial Secretary and not to the Manager

The **TELEPHONE NUMBERS** of the British Medical Association are MUSEUM 9861, 9862 9863, and for *British Medical Journal* and Supplement Manager (internal exchange, four lines)

The **TELEGRAPHIC ADDRESSES** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, Attology Westcent London

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc) Articulate Westcent London

MEDICAL SECRETARY, Mesecra Westcent London

The address of the Irish Office of the British Medical Association is 16 South Frederick Street Dublin (telegrams *Bacillus, Dublin* telephone 62559 Dublin), and of the Scottish Office 7, Drumsheugh Gardens Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Lymphadenoma

"PRACTITIONER" writes Can any of your readers suggest treatment for a young man with lymphadenoma The cervical glands are the only Principally involved but his chief disability is due to the fact that his disease is associated with the Pel Ebstein syndrome and for four or five days every three weeks the patient is practically incapacitated by pyrexia and malaise

Oxaluria

Professor A C Frazer Physiological Laboratory St Mungo College (Glasgow) writes If Inquirer (October 10th p 685) would send to me here a sample of the patient's urine passed at 10 p m then two days after another sample of his urine passed at the same time but having that day partaken of a liberal quantity of sweetened diet I perhaps may be able to help him The so-called oxaluria has undergone modification in its origin

Survival after Prostatectomy

Dr Geo P Coldstream (Brondesbury) writes I am glad to be able to tell Mr Dickie of a patient of mine who is 94 years and 6 months of age The late Mr Openshaw removed this man's prostate in October, 1907.

Income Tax

Retirement Cash Receipts

"W P" retired from a partnership as from June 30th, 1930, and took up medical work in another part of the country He has been informed that he will be assessed on the amount of the payments made to him in respect of work done before that date, but not paid for when the last cash account was made up

*** In our view this is incorrect The liability for income from the new work must be calculated without reference to the former income, and the latter should be calculated, as far as "W P" is concerned, just as if he had retired The true basis of liability is the value of the year's bookings, but where the income is reasonably steady year by year the cash income must be approximately the same as the value of the bookings, and is then acceptable on grounds of convenience But just as his bookings cease at the date of withdrawal, so it must be assumed that his cash receipts cease, otherwise the cash basis becomes unfair to the taxpayer That basis is not allowed during the first two or three years of a practice, and the tax is then paid on an amount greater than the cash receipts The revenue should not, therefore, now have tax on the final cash receipts, or it will receive a total tax in excess of what is due

Establishing a Residence in this Country

"Member B M A" has been resident abroad in the past, but has visited this country at, roughly, two yearly intervals In April, 1932, he will take up permanent residence here, and up to August will be receiving pay through the Colonial Office On what basis will he be assessable for 1932-33?

*** On the amount of his income for that year, the previous year's basis does not apply to 1932 33 in the circumstances

"Unity" explains that A intends to take over B's practice as from November 16th, 1931 How should the income tax liability for 1931-32 be dealt with?

*** We presume that A is acquiring the whole and not merely a share of a practice In that case B's liability for adequate period April 5th to November 16th 1931 will be determined by his actual earnings during that period and A will be assessed as having commenced a new practice as from November 16th The method of splitting the assessment for the initial year applies only to cases where one partner remains in the new firm

LETTERS, NOTES, ETC.

Treatment of Varicose Veins

Dr D Montgomerie Paton (Kilmore, Victoria, Australia) writes For many years I had a large experience in treating varicose ulcers, and the following methods gave 95 per cent of successes For varicose veins below the knee (when too inflamed for a bandage) absolute rest in bed and, orally, 1 drachm of low potency anti-diphtheria serum three or four times a day (200 to 250 units per c cm, B W and Co) The serum is a panhormone medium carrying the animal's complete hormone content for defence and repair of tissues in the presence of the paralysing and proteolysing action of diphtheria toxin on the tissues The bandage was a two and a-half-inch white cotton elastic one, which allowed the skin to "breathe," and kept it dry The length was regulated by the weight of the patient When this bandage was continuously applied it removed all the symptoms of varix, and in time the veins returned to their normal condition If any patient returned, it was through failing to bandage properly, discontinuing prematurely, or wearing the bandage after all the elastic had perished For varicose ulcers all patients were sent to bed, except in those occasional cases favourable to ambulatory treatment They were all treated with the same serum and the same dosage, and were visited generally once a week The ulcers were dressed with normal or anti diphtheritic serum (low potency) or with boric fomentations These were applied on lint cut to the size of the ulcer and covered with oiled silk, with a margin of a quarter of an inch This kept the skin dry The dressing was changed by the patient two or three times a day With this treatment the most callous ulcer began to show, in a short time, granulations, which progressed to complete healing The bandage completed the treatment, but the patient had to continue its use permanently My record case was that of an old lady of 82, who had a varicose ulcer under the outer malleolus for over fifty years This was completely healed, but as she refused to go on wearing the bandage the ulcer broke down, and was again successfully healed. Her family attended to the bandage after that

Phimosis and Circumcision

Dr A. T Brand (*Driffield*) writes. The routine circumcision of male babies, which is so fashionable, is a most objectionable craze, and an unjustifiable mutilation When there is no phimosis, circumcision is obviously uncalled for Where it does exist a simple operative measure which involves no mutilation nor loss of tissue, is available This measure is fully described in my book, *Clinical Memoranda* (Baillière) in the article on "Phimosis" (p 195), so it need not be repeated here

Antimony in Lymphoid Hypertrophy

Dr T P Sturm (Leigh, Lancs) writes As a practitioner who for many years has enjoyed exceptional opportunities of observing the adenoid child, I wish to record an observation which I believe to be of interest In certain cases of simple hypertrophy of the pharyngeal lymph ring in children so marked an improvement follows the administration of small doses of antimony that operative treatment occasionally becomes unnecessary This is an observed fact which seems worthy of further investigation Upon purely clinical grounds I have arrived at the conclusion that antimony enables the tissues of "the catarrhal child" to regain or acquire some power of calcium fixation, the loss of which appears to be the cause of lymphoid hypertrophy

Radiation Therapy

Dr Arthur H Laird (Coventry) writes I have read with interest the review of Dr Kaplan's book on *Practical Radiation Therapy* in the *Journal* of October 3rd The review states "There is scarcely a human ailment for which x rays are not suggested as a cure, and the headings of 'Asthma,' 'Pertussis,' and 'Malignancy of the nose' taken at random, will illustrate the extent to which the author's faith has carried him" The word "however" in the next sentence suggests to me that the sentence above quoted is intended to be taken in the light of rather adverse criticism This seems to me rather like putting one's money on the wrong horse Radiotherapists in this country know quite well that the value of *x* rays as a therapeutic agent is not sufficiently recognized by the average practitioner For example, how many are aware that x rays shorten the coagulation time of the blood? Cases needing operation in which an oozing of blood is to be feared would benefit by x-ray therapy previous to the operation But how many such cases ever reach the x-ray department of our hospitals? I venture to say, very few Further, how many of us know that x rays is the treatment *par excellence* for such conditions as acne indurata, Bazin's disease, or excessive localized sweating? I may add that Dr. Kaplan does not claim x rays as a cure for asthma I quote from his book "In some cases x rays relieve this condition" My own personal experience absolutely justifies such a statement

Lord Derby Hospital for Women

Dr J B Higgins writes I find my name has appeared on the list of the staff of the Lord Derby (St Margaret's) Hospital for Women, Manchester, as the honorary radiologist This is an error, and I have taken steps to have my name removed

Marylebone Parliamentary Election

Dr Arthur Whitfield (London, W 1) writes May I trespass on your space in order to answer numerous inquiries without sending individual replies? I am *not* standing for Parliament as a Socialist candidate in this neighbourhood It is true that, after reading Socialists' speeches and noting their actions, I am apt to "see red," but I have no intention of standing or voting for that colour.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 44, 45, 46, 47, 50, 51, 52 and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 239

BROOKMANS PARK STATION (L N E R main line) Tavistock Square, W C 1

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

364 Tabes in Early Life

W Pires (*Rev. Sud Americana de Med et de Cirurg.*, July, 1931, p 711) regards juvenile tabes as not altogether a rare disease, failure to diagnose it is often due to the fact that it exists without the familiar well defined signs of the adult form of the disease, Rombergism, loss of deep sensibility, and astereognosis being often not marked Optic atrophy is a very important sign, found in 20 out of 34 reported cases incontinence of urine is a suggestive and frequent indication The Argyll Robertson pupil, generally present, is definitely diagnostic of the condition, whereas abolition of the deep reflexes of the lower limbs is common to Friedreich's ataxia and peripheral neuritis, in the differential diagnosis from congenital ataxia, the increased deep reflexes of the latter condition afford a clue except where the diseases coexist Serological tests should always be employed Amaurosis and cerebral disturbances are the most common troubles which bring to notice juvenile tabes, but all symptoms and signs of the adult form may be found Pires reports two cases *in boys 12 years old, in both there was optic atrophy*, incontinence of urine, and lightning pains In one case, in which there was also well marked ataxia, great benefit followed malarial therapy including improvement of the vision, in the other case, where malaria therapy was refused the headache disappeared after a single injection of N A B and bismuth Pires emphasizes the need for watchfulness in diagnosing the condition, while still amenable to treatment

365 Mental Derangements in Hypothyroidism

Ethelene P Hayward and A H Woods (*Journ Amer Med Assoc*, July 18th, 1931, p 164) discuss mental derangements in hypothyroidism, with special reference to their misleading influence on diagnosis This condition sometimes shows its most striking effects through interference with the function of the brain cells The patient may lapse gradually into depression and an anxiety state thought may become slow and bodily movements retarded and the condition is easily mistaken for the depressed type of psychosis Alternatively, there may be irritability and excitement leading to a diagnosis of mania Patients may manifest thought distortion with such bizarre hallucinations and delusions that dementia praecox is erroneously diagnosed In these psychotic cases the physical signs of myxoedema may be present and yet be easily overlooked This is partly due to an insufficient psychopathic knowledge on the part of the physician, and also to the fact that the patient's mental attitude sometimes renders a physical examination difficult or impossible

366 Subacute Influenzal Endocarditis

S A Lofwenberg and H L Goldburgh (*Med Journ and Record* August 5th 1931, p 115) report a case of subacute bacterial endocarditis, with the necropsy findings and a description of the blood culture technique adopted for its recognition The condition is of comparatively rare occurrence An unmarried woman, aged 24, was admitted to hospital on the provisional diagnosis of typhoid fever She complained of fever, headache, weakness, and an infection of the hands, she gave a history of typhoid fever when 7 years old, and of two moderate attacks of chorea later In 1918 she was confined to bed for a fortnight with influenza, and each winter for the last four years she had had attacks of acute tonsillitis Her present illness began with fever and sweating followed by lumbar pain severe headache, moderate nose bleeding, and deafness in the left ear, without any evidence of involvement of other nerves On admission to hospital a provisional diagnosis of subacute bacterial endocarditis was made on account of the history irregular fever, the presence of systolic and regurgitant mitral murmurs enlarged spleen, and the development of petechiae on the skin of the trunk and extremities, with embolic phenomena in the left ear and fingers In spite of the severe manifestations the patient felt well, but gradually became worse until she died forty days after the onset The ultimate diagnosis of subacute endocarditis caused by haemophil influenzal infection was based upon the fact that the organism (*Haemophilus influenzae*) was recovered from the blood and throat culture during life, and from the mitral valve vegetations and blood of both ventricles after death The value of persistent search and repeated blood cultures was shown by the fact that only one out of the six blood cultures in this case yielded a definite growth of the organism.

367 Purpura Haemorrhagica following Diphtheria

J D Rolleston and D G Matthewson (*Clin Journ*, August 5th, 1931, p 370) record a fatal case in a boy, aged 4 years, who after a moderate attack of diphtheria treated by antitoxin developed suppurative cervical adenitis Ten days later an urticarial serum rash followed, *accompanied by swelling of the scrotum* due to fluid in the tunica vaginalis Five days later double otorrhoea ensued, bleeding took place from the mouth and pharynx, and the stools were black On the next day the child showed petechiae and purpuric patches on the abdomen and loins, as well as haemorrhages from the mouth pharynx and rectum The heart hitherto normal developed a cantering rhythm and death occurred next day The necropsy showed numerous haemorrhages in the pharynx and oesophagus the submucous coat and external surface of the stomach the small and large intestines, the liver kidneys bladder and heart The case was of interest first because of the great rarity of purpura haemorrhagica in diphtheria apart from the acute stage and secondly on account of the possible relation of the purpuric eruption to antitoxin Only four previous cases of purpura haemorrhagica in convalescence from diphtheria had been recorded, and all the patients had recovered It was unlikely, that the purpura was due to antitoxin since 24 other patients had had the same brand of antitoxin, but none had shown any evidence of purpura

Surgery

368 Fixation of Iliac Colon by Acquired Bands

A C Jordan (*Brit Journ Radiol*, August, 1931, p 387) describes the methods by which fixation of the iliac colon in the left fossa, and the resulting mechanical obstruction can be radiographically demonstrated Such fixation is an acquired condition, often commencing in infancy as the result of constipation and chronic intestinal stasis it increases in extent if constipation persists until in the adult it may involve three or four inches of the iliac colon By restricting the mobility of the iliac colon the free passage of faeces is prevented so that distension of the proximal colon and caecum takes place with inflammation of the mucous membrane spasm of the muscular coats limiting the calibre of the lumen and consequent partial obstruction to the passage of faeces with resulting secondary changes leading to such complications as peritonitis and duodenal ulcer The condition and its extent are easily recognized with the fluorescent screen after a barium enema when an accumulation can be seen above and below the anchored segment this appears empty or nearly so since the fluid has been extruded from it by contraction of its muscular coats as soon as the distending pressure of the enema has been relaxed If some of the enema is now allowed to run out of the rectum, the evidence of

obstruction is emphasized, since a considerable amount is retained above the constricted portion, causing dilatation of the descending colon; the appearance of the dilated descending colon ending abruptly at its junction with the tethered portion is very characteristic. The consequent retention and irritation of solid faecal matter above the obstruction is regarded as a reason for the iliac colon being one of the most usual sites for cancer, and the condition gives rise to manifestations of digestive disorder and toxaemia.

369 Osteomyelitis of the Hip-joint

R. Sodur (*Rev. de Chir.*, June 6th, 1931, p. 377) reports 49 cases of osteomyelitis of the hip, and gives radiograms of 22 of these cases. He points out that, although common in infancy it occurs less frequently in childhood and adolescence, and is rare in adult life. The general belief is that the origin of the disease is by bacterial embolism, but the author suggests that a generalized infection may be the etiological factor. The lesion at the onset of the infection may be synovial, but is more often bony. In comparing the progress of the disease in the various groups, it was found that the difference depended upon the amount of bony tissue present. In infancy, when there is little bony material, the osteomyelitis develops into an abscess without ankylosis. In adolescence, when there is much bony substance, ankylosis is usual. The 49 cases reported are classified into three groups. The first group comprised 17 cases of osteomyelitis contracted in early infancy. In these the onset was acute, and usually occurred during some infectious disease such as influenza or tonsillitis. Sometimes an abscess develops at the top of the thigh, and this has to be opened. In most cases this heals, and all appears to be well until the child begins to walk, when partial congenital dislocation of the hip is noticed. Treatment should consist of drainage and extension during the acute stage, to avoid, if possible, the partial dislocation. If this occurs, efforts at reduction should not be made until at least a year after the cessation of the active process. In some cases an operation is necessary; this consists in the fixing of the hip-joint by means of a bony buttress. The second group is defined as osteomyelitis of the closed type, contracted in childhood or adolescence; in the 12 cases encountered the onset was acute, with pain in the joint, contraction, and muscular spasm. The symptoms in these cases generally persist for some weeks, and the diagnosis is difficult since the condition approximates closely to tuberculosis, osteochondritis, or arthritis. Treatment should take the form of immobilization and drainage during the acute stage, resection of the head of the femur being reserved for very severe cases. After growth is over, the defective position is treated by tenotomies and osteotomies, and the ankylosis by arthroplasty. The third group—osteomyelitis of the open type during childhood or adolescence—occurred in 20 cases, and the condition was associated with suppuration. The pus was seldom evacuated spontaneously, but, following surgical intervention, the symptoms were quickly relieved. The prognosis is favourable, but recurrence is possible, and when this happens no satisfactory treatment has been found.

370 Osteochondritis Dissecans

K Kissel (*Chirurgja Narzadów Ruchu i Ortopedja Polska*, 1931, vol. iv, Fasc. 2, p. 115) reviews the recent theories concerning the cause of osteochondritis dissecans (Koenig) and expresses the belief that the disease begins as a local aseptic necrosis in the epiphysis. The starting point of the necrosis is an embolus in the epiphysis, originating from a thrombosis of the afferent artery supplying the corresponding segment; this thrombosis may be caused by an injury. The disease has two stages. In the first, when the necrotic focus is still in the epiphysis, there are very few specific symptoms. The second stage, when the necrotic focus has separated into the joint, is characterized by attacks of sudden pain due to jamming of the free articular body between the articular surfaces. In both stages diagnosis is possible by means of *x* rays. In the first stage of the disease the author advises expectant treatment, until the free body separates into the joint; in the second stage an operation is essential. Excellent results without any complications have been obtained in seventeen cases operated on for removal of such free articular bodies from the knee and elbow joints.

371 Familial Elephantiasis of the Gums

A. Mirolli (*Arch. Ital. di Chir.*, June, 1931, p. 401) reports, with photographs, two cases of marked hypertrophy of the gums. The patients, a man aged 28 and his aunt aged 70, were members of a family in whose history this abnormality of the gums was unusually prevalent, for out of 29 members no fewer than twelve were affected in the same way in various degrees. Consideration of the ancestry left the author in doubt as to whether any Mendelian influence could be traced. In all the cases the affection did not start until the second dentition, and there was very little evidence of disease in the teeth themselves. Discussing the various theories propounded to explain these cases, the author is inclined to believe that in his cases a probable explanation was some defect in the hypophysis; this was partly supported by the acromegalic appearance of the aunt. In spite of the rarity of this condition, the author has been able to collect over 50 references from medical literature. In one case salvarsan was said to be useful. Removal of portions of the affected gum showed definite thickening of the epithelium and chorion with slight infiltration.

Therapeutics

372 Continuous Pollen Desensitization

W. T. Vaughan (*Journ. Amer. Med. Assoc.*, July 11th, 1931, p. 90) has employed perennial pollen desensitization, in addition to treatment during and before the seasonal incidence, for the past four years. During 1930 he utilized the three methods in 57 cases, and obtained good results in 21 treated by the perennial form, though some failures were recorded among those treated by the other procedures. He records one case in which there has been no recurrence of ragweed asthma after two years of perennial treatment, concluded in December, 1929. The technique (based on experience of patients in Virginia) consists in building up the patient's resistance with about twenty doses, beginning with a 1 in 5,000 dilution, and increasing to a maximum of 0.5 c.cm. of a 1 in 50 dilution, or until the skin reactions are negative. Throughout the season maximal doses are continued or slightly smaller ones, at intervals of one or two weeks, or, if the symptoms are not relieved, more frequently. After the season, the dose is 0.1 c.cm. of the 1 in 50 dilution, given at intervals of one to four weeks; Vaughan prefers two-weekly intervals. Two or three months before the season, the dose is increased by 0.1 c.cm. of each pollen extract used, up to the maximum. In changing from an old to a new batch of pollen extract, it is advisable to mix the extracts, with a gradually increasing proportion of the new, since reactions may follow the use of more potent allergens. In addition to the obviously greater convenience of spreading pollen desensitization over the year, and the avoidance of dangerous attempts at "rush desensitization" during the season, in sensitive persons, the perennial administration appears to improve the general health of pollen asthmatics out of the season. It acts possibly as a non-specific protein therapy, which lessens the tendency to asthmatic attacks due to infections in winter, or to protein irritants other than pollen. The method also affords a means of beginning treatment of pollen asthma at any time of the year.

373 Salt-free Diet in Psoriasis

O. L. Levin and S. H. Silvers (*Med. Journ. and Record*, August 19th, 1931, p. 179), in a preliminary report, advocate the treatment of psoriasis by means of a salt-free diet; they describe three successful cases. As the result of studying the physiology and chemistry of the

BROOKMANS PARK STATION (L.N.E.R. main line). Tavistock Square, W.C.1.

perspiration in such cases, it was observed that the psoriatic lesions did not sweat, that the acidity of the sweat in other areas was increased, and that there was a distinct tendency to a higher concentration of the chlorides in it. On the basis of these facts the patients were put on a diet consisting mainly of vegetables, fruits, cooked cereals, cream, salt-free bread, cottage and cream cheese, fish, an occasional lamb chop, coffee, and tea. Sweat baths were given to hasten the elimination of salt, and local applications of cold cream, and occasionally of 3 per cent. boric ointment, were adopted. Hospitalization for better control and closer observation is advisable. Encouraging results were obtained in all three patients who had suffered for the previous three years from obstinate forms of the complaint on the extremities, trunk, and scalp resisting the usual methods of treatment. So far there have been no recurrences in any of the three cases reported, the first patient having been free for over seven months; favourable results are being noted in the patients now under observation, especially in those under close supervision. The authors consider this preliminary report justified in order to enable others to try the same lines of treatment.

374 The Rate of Absorption and Elimination of Bismuth

N. Yernaux (*Ann. de Derm. et Syph.*, July, 1931, p. 761) has studied the rate of absorption of bismuth from the tissues by means of radiographical estimations of the masses of drug at the seat of entrance. He finds that there is a time factor which, in the case of bismuth subgallate, is equal to fifty-six days—that is to say, every fifty-six days after injection the amount of bismuth left unabsorbed is reduced by one-half. This can be represented graphically by a decreasing geometrical curve. Other bismuth preparations were found to have different time factors. Again, examination of the analyses of the excretion of bismuth from the body renders possible the construction of similar curves, so that finally complete courses of treatment can be represented graphically, showing the amount and availability of the bismuth in the body. These curves are given in the case of bismuth subgallate (10 per cent. to 15 per cent.) in oily solution, the preparation favoured by the author because it is completely absorbed without encystment, and can be given subcutaneously without pain; its rate of absorption is known, and the intensity and duration of its therapeutic activity can be estimated; and, lastly, it is eliminated equally by the faeces and by the urine, thus protecting the kidneys.

375 Arsenic in Chronic Myelogenous Leukaemia

Potassium arsenite apparently has a specific effect on the haematopoietic organs, and 9 out of 10 cases of chronic myelogenous leukaemia reported by C. E. Forkner and T. F. McN. Scott (*Journ. Amer. Med. Assoc.*, July 4th, 1931, p. 3) showed striking improvement after its oral administration. In one case, in the terminal stage of the disease, no benefit was noticeable. In the remainder the leucocyte count was reduced to approximately normal; the immature cells were markedly reduced, and in some cases disappeared from the blood. The anaemia was arrested, and in several cases the erythrocytic and haemoglobin values became almost normal. The monocytes and basophilic granulocytes relatively increased, and the number of nucleated red cells rose. The size of the spleen and liver was reduced in each case, and in two patients these organs were no longer palpable. Biopsy of the bone marrow suggested a return to red marrow; and the basal metabolic rate decreased to nearly normal figures. Most of the patients improved in weight and general condition. These observations suggest that potassium arsenite is of definite value in the palliative treatment of chronic myelogenous leukaemia. The best results were obtained by the rapid administration of the drug until the desired effect was produced, or signs of intoxication occurred; it was then discontinued for four to six days, and resumed in small daily doses.

Dermatology

376 Carotinaemia Resulting from Restricted Diet

O. L. Levin and S. H. Silvers (*Journ. Amer. Med. Assoc.*, June 27th, 1931, p. 2190) report two cases of non-diabetic carotinaemia which were discovered in a dermatological practice. Most of the cases of carotinaemia (lauran-tiasis cutis) reported in the literature have occurred in diabetic patients and children. The substitution of a vegetable diet for animal foods, which was a widespread practice after the war, was responsible for an increase in the number of people suffering from this disturbing though innocuous condition. The modern dietetic treatment of various diseases and the personal endeavours of patients to reduce adiposity have recently caused more cases to be noted. One of the cases now reported occurred in a woman who had placed herself on a restricted diet for a year, and complained of a gradually increasing yellowish discoloration. There were no other cutaneous complaints, and pruritus was absent. The palms were more deeply yellow than the rest of the body. After limiting the vegetable diet the pigmentation gradually faded, and entirely disappeared. The second patient had been under treatment for acne vulgaris, *x*-ray therapy being combined with internal medication. She had lit her diet almost entirely to vegetables, and had eating at least one pound of carrots and several ora daily. The yellow pigmentation was uniform, except the palms and soles, where it was more pronounced. sclerae and mucous membranes were normal. The ser was an intense golden yellow, but van den Bergh's reacti was negative. In order to emphasize the relationsh between the pigmentation and the diet the patient w asked to increase the amount of carrots and the numb of oranges consumed daily. At the end of two week the deepening and extension of the pigmentation were evident. A month after discontinuance of these foods the pigmentation had noticeably diminished, and in another two weeks had entirely disappeared. Carotene occurs abundantly in nature as an exogenous pigment. It is present in carrots, pumpkins, yellow turnips, parsnips, spinach, lettuce, green and yellow beans, kale, oranges, and eggs. The yellowish colour of butter-fat and subcutaneous fat is also due to carotene, but a diet must be essentially vegetarian to produce carotinaemia.

377 Pityriasis Folliculorum

H. Lawrence and R. Brodie (*Med. Journ. of Australia*, May 2nd, 1931, p. 529) record four cases of a form of skin infestation defined by S. Ayres as "pityriasis folliculorum (demodex)." In this condition there are blotchy areas of the skin of the face and neck, without scaling, but containing large numbers of the *Demodex folliculorum*, a hexapoid parasite. The authors believe that these demodex infections are probably more common than is at present recognized, and that they occur in 0.5 per cent. of all cases of skin diseases in private practice. The treatment recommended is a cleansing lotion containing a mixture of boric and salicylic acids; this is followed by a strong parasiticide ointment composed of camphor, ammoniated mercurial ointment, and spirits of wine. In one instance in which the condition was resistant to treatment, the application of ultra-violet light, followed by fractional doses of *x* rays, proved effective. The demodex concerned in this condition appears to be of a different type from the variety which has been found in some cases of impetigo.

378 Dermatitis from Sweat Bands of Hats

D. I. Macht (*Urol. and Cut. Rev.*, June, 1931, p. 445) records the case of a physician who in two successive years developed severe dermatitis of the forehead with formation of pustules, following the use, on the first occasion, of a Panama hat, and on the second of a Leghorn hat. Extraction of the sweat bands with alcohol and ether led Macht to the conclusion that the bands were finished with a nitrocellular lacquer containing some irritating pigments.

Obstetrics and Gynaecology

379 Ectopic Decidual Tissue in Absence of Pregnancy

J. Schereschewsky (*Arch. f. Gynak.*, March 6th, 1931, p. 241) states that nests of decidual cells have been found during pregnancy in the ovaries, oviducts, pelvic peritoneum, omentum, appendix, and pelvic lymph glands, and also in hernial sacs and in polypi of the cervix or corpus uteri. Such ectopic decidual tissue has been reported in the absence of pregnancy by Schiller, and also by Frankl in a patient aged 54. In a case described by Schereschewsky, a woman, aged 32, shortly after abortion was found to have a polypus protruding into the posterior fornix from a node of ectopic endometrioid tissue in the recto-vaginal septum. The polypus contained scanty gland tissue in a stroma of decidual cells; its structure was similar three months later, after recurrence. The persistence of the decidual reaction is attributable to hormonic influence from the corpus luteum of menstruation.

380 Intramural Pregnancy

V. Malvieff (*La Gynecol.*, June, 1931, p. 337) records two cases of intramural pregnancy. Owing to the rarity of such occurrences, and their complex symptomatology, a precise diagnosis before laparotomy is generally impossible. In 216 laparotomies (Kiev) on abnormally situated pregnancies, only 2 of these were intramural, one being "pure," the other "mixed." The history of these two cases is given in full. The first patient was in perfect health, had had three normal pregnancies previously, and then developed an acute inflammation of the adnexa which was rapidly cured. Several months later the interstitial pregnancy occurred. At the laparotomy the abdominal cavity was found to be full of blood, the ovaries and tubes were normal on both sides. At the left angle of the uterus was found a tumour of the size of a hen's egg. At the site where the tube joined the uterus there was a small rupture, 7 mm. in diameter and 4 mm. deep. Microscopical section of the tumour revealed decidual cells and chorionic villi in the muscular tissue. The cause of the rupture appeared to be complete penetration of all the coverings by chorionic villi. In the second case the woman had been married six months. One period was missed, and then a midwife gave two intrauterine injections of a solution of iodine. One month later the patient was brought to hospital with every appearance of abdominal shock. At the laparotomy blood was found in the abdominal cavity, and a tumour with a ruptured wall was discovered at the left angle of the uterus. Microscopical examination revealed chorionic villi and islets of decidual tissue in the tumour. The coverings consisted of muscle and uterine tissue. Since this patient was a primipara special note was taken as to whether there was a congenital infantilism of the tubes, but nothing abnormal was found. It was natural to suppose that the intrauterine injections of iodine were an etiological factor in this case.

381 Diagnosis of Ruptured Extrauterine Pregnancy

A usual diagnostic method in doubtful cases of ruptured extrauterine pregnancy is puncture of Douglas's pouch. G. Hubinont (*Bruxelles Médical*, August 16th, 1931, p. 1229) points out that the long needle necessary for this operation is not always at hand, and describes a method of entering the pouch through the left iliac fossa, in which an ordinary short needle can be used. The skin, after disinfection, is punctured perpendicularly, and the needle then penetrates the aponeurosis and the muscles, as in regional anaesthesia. This procedure should be conducted cautiously until the peritoneum is reached. The needle is then inserted a few millimetres deeper, and aspiration is begun. Hubinont claims that this method is easier, quicker, less painful, and in certain cases, such as rural confinements, of more assured asepsis than puncturing through Douglas's pouch. A case is recorded in which this diagnostic procedure was successfully employed.

Pathology

382 Detection of Tubercle Bacilli in Stained Films

J. E. Pottenger (*Journ. Lab. and Clin. Med.*, July, 1931, p. 985) has endeavoured to ascertain the length of time that gives the highest proportion of positive results under practicable conditions in searching for tubercle bacilli in stained preparations. The sputum was prepared in various ways; in some cases direct smears were made, in others antiformin was used or a concentration method involving the use of a hydrocarbon, while shaking was done either with or without enrichment, no fewer than [illegible] were stained for fifteen minutes; if [illegible] various degrees. Considera record was made of the author in doubt as to whether and the minute in could be traced. In all the cases 440 specimens were part until the second dentition, and results of differen[illegible] evidence of disease in the teeth as strictly comp[illegible]ing the various theories propounded a tubercle bacillus, the author is inclined to believe of shaking and th[illegible]obable explanation was some defect ting the groups this was partly supported by the acro- less evenly distri[illegible] the aunt. es, and obtaine[illegible]

V. de Lavergne and R[illegible]al form, thou[illegible] *Méd.*, May 6th, 1931, p. 651) find that the duration of the incubation period of spirochaetosis icte[illegible]haemorrhagica in man varies according as it is contracted from water or is of surgical origin. In the former case the incubation is very short, averaging about four days and rarely exceeding ten while in the latter the period is longer, being on the average about fifteen days, and almost always more than ten days. This difference is due to the duration of the incubation period depending mainly on the number of infective organisms and their virulence. In the case of infection due to water a much larger number of organisms are introduced into the system than by any other mode of penetration.

384 Cardiac Output and Oxygen Utilization

I. Harris and I. J. Lipkin (*Edinburgh Med Journ.*, September, 1931, p. 501) report the results of investigating a series of cardiac patients of different kinds, with special reference to the physiological and functional disturbances which were present. They conclude that, apart from gross heart failure, it is impossible to distinguish between a normal and a diseased heart from cardiac output determinations alone. Output values obtained under working and resting conditions are, however, useful in estimating the degree of reserve power, which is highest when the difference between the two sets of values is smallest. There is an inverse ratio between the cardiac output and the utilization of oxygen; this is particularly marked when the output values after work are compared with the corresponding percentage increase of oxygen utilization. The increase of stroke volume that results from work, when related to the greater oxygen utilization, gives a clear indication of the cardiac reserve power. The normal individual reacts to exertion as far as possible by an increase in the stroke volume; the cardiac patient reacts more particularly by a rise in the pulse rate. Auricular fibrillation is characterized by a high percentage of oxygen utilization.

THE RELIEF OF TOXIC HEADACHES

In addition to these headaches directly traceable to some ocular, nasal, aural, dental or circulatory lesion, there are even more cases in which no structural or functional abnormality is apparent. Of these, a very large number are due to blood toxicity. Such poisoning is not necessarily bacterial in origin, being more frequently due to the retention of waste or perverted products of metabolism that should have been promptly eliminated.

Many people suffering from this sort of headache obtain great relief from a morning draught of Eno's "Fruit Salt" which, by promoting intestinal peristalsis, eases the traffic congestion throughout the body. It is not suggested that headache is often directly caused by the absorption of bacterial toxins from the alimentary canal, for evidence as to such absorption is inconclusive; but the fact that relief so promptly follows the emptying of the lower bowel suggests that a hold-up at any part of the body's physiological sequence tends to slow down the whole.

Eno's "Fruit Salt," it may be mentioned, contains no trace of sulphate of soda or of magnesia. It is refreshing and agreeable to the palate, although no sweetening or flavouring agent is added.

ENO'S "FRUIT SALT"

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

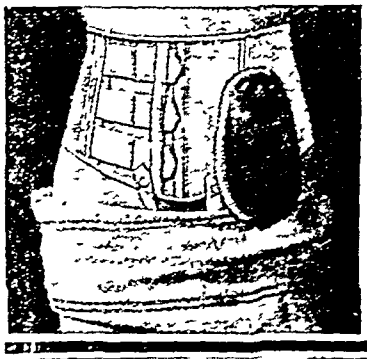
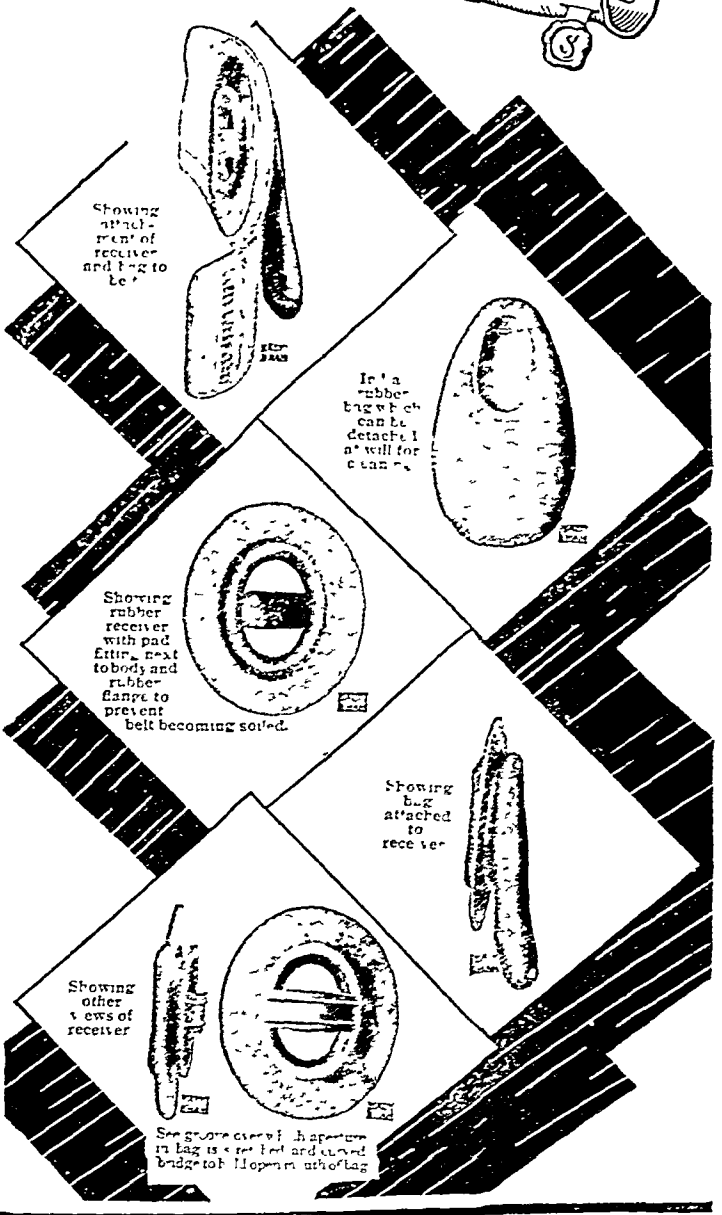
Salt and Son Ltd

SALT'S PATENT COLOSTOMY BELT



The necessity of wearing a Colostomy Belt is an ever present source of embarrassment to the patient



All undue apprehension on the patient's part is however, largely overcome by the personal comfort and hygiene afforded by Salt's Colostomy Belt

Note these advantages:—

1. Moulded rubber receiver, sterilizable by boiling.
2. Mouth of Bag kept open for free entry of Faeces.
3. Easy removal and cleaning of Bag *without removal of Belt.*
4. No crevices to hold Faeces, and therefore little odour.
5. Less bulky and more sanitary than any other.
6. Rubber portions far more durable than in the old style of belt.

N B—A belt is also made with special cup instead of bag for cases where the faeces are of a more solid nature.

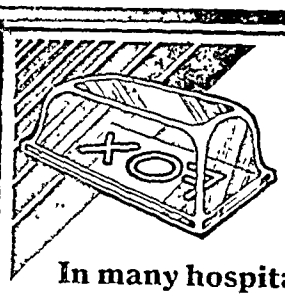
"The Rose Corset-Belt"



for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

CHISWICK HOUSE, PINNER, MIDDLESEX.
Telephone: PINNER 234.
A modern country house, 12 miles from Marble Arch, in beautiful and secluded grounds.
Fees from 10 guineas per week.
Voluntary Patients received for treatment.
Special provision for "Temporary" patients under the new Mental Treatment Act.
DOUGLAS MACAULAY, M.D., D.P.M.

BARNWOOD HOUSE, GLOUCESTER.
A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L.M. & S. Railway Stations at Gloucester the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.
Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.
For particulars as to terms, etc., apply to—
ARTHUR TOWNSEND, M.D., Medical Supt.
Telephone, No. 7 Barnwood

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.
FOR THE UPPER AND MIDDLE CLASSES ONLY.
President, THE MOST HON. THE MARQUESS OF EXETER, C.M.G., V.D.C.
Medical Superintendent DANIEL F. RANKIN, M.A., M.D.
This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or who are in the early stages of attacks of mental trouble, temporary patients and certified patients of the better class are received for treatment. Careful clinical, mental, laboratory, clinical and pathological examinations. Private rooms with special nurses, table d'hôte, to the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.
This is a Reception Hospital in detached grounds with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy, various medicated baths including Turkish and Russian baths, the principal Continental Mineral Waters, Vichy Douches, Scotch Douche, Electrical baths, Pneumatics treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for bacteriological, chemical and pathological research.

MOULTON PARK.
Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and parts of Moulton Park. One patient branch is a feature of this branch and patients are given every facility for occupying their lives in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.
The private house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short stay, change or for longer periods. The Hospital has also a private bathing house on the seashore. There is trout fishing in the park.
At all the branches of this Hospital there are ample grounds for ball and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own garden, and facilities are provided for hand crafts such as carpentry, etc.
For terms and further particulars apply to the Medical Superintendent (Telephone No. 80, Northampton), who can be seen in London by appointment.

WOODLANDS PARK
GREAT MISSENDEN BUCKS.
550 feet above sea level on Southern Chilterns. 30 miles from London. 90 acres, Gardens, Woods, & Park.

Telephone 91 Gt. Missenden. Apply C. W. J. BRASHER, M.D.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.
Physician: H. Ashton, M.R.C.P. (Edin.), Makerfield.
For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.
Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.
This Institution is exclusively for the reception of a limited number of *Private Patients of both sexes of the Upper and Middle Classes* at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.
Tel. 64117. *For terms, etc., apply to the Medical Superintendent.*

TYKEFORD ABBEY, NEWPORT PAGNELL, BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.
An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.
The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton and 12 miles from Bletchley on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Patients to Northampton Road fifty miles from London. Both sexes are accommodated. Patients Therapeutic Treatment is used entirely in suitable cases. Radiant Heat, X-Rays, and Ultra-violet Light. Bath rms. and Foam Baths. Billiards, tennis etc. Fees from five gns. per week.
Apply, Dr. D. E. M. DOUGLAS MORRIS. *Telephone* Newport, Pagnell 121.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).

President: Lord Wakefield of Hythe, C.B.E., LL.D.
Treasurer: Sir Lionel Faudel-Phillips, Bart.
Physician-Supt.: J. G. Porter-Phillips, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week, beginning on October 19th, 1931.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings; all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—The Secretary, Ruthin Castle, North Wales. *Telegrams*: Castle, Ruthin. *Telephone*: Ruthin 66

Once "A CONTINUAL ANXIETY— CONSTIPATED, CRYING & PRACTICALLY NO WEIGHT—"

January 21st, 1931

Dear Sir,

I enclose herewith a photograph of my son taken during the last few days.

He was born on April 17th, 1930, and weighed six pounds at birth. He is now 9 months old and weighs a little over 24 lbs., has six teeth and has the happiest disposition one could wish for.

He was breast fed during the first fortnight, and then put on ——— and ——— and raw cow's milk in turn. For the first month of his life he was a continual anxiety, constipated, crying and practically no weight. At one month he was put on Cow & Gate on the advice of my sister, a Health Visitor at Bicester, and from the first feed he improved. He slept the first night he had Cow & Gate from 7 p.m. till 7 a.m. with a feed at 11 p.m. which he took sleeping. From that date we hardly knew we had a baby, and it has been a delight to watch him grow. His teeth gave him very little trouble, and as you can see he has firm flesh, really fine bones, and no excess fat.

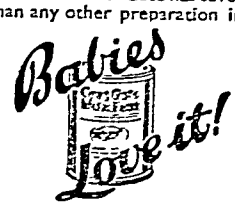
All this we thank your food for, and we feel that it is only fair to mention it. If his photo is of any use to you, please use it, but do not advertise his or my name, as my father is a Doctor and it might cause him embarrassment.

With many thanks for his health,

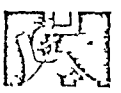
Yours very sincerely,———

¶ Clinical Samples of any of Cow & Gate's Products, will gladly be sent on request to members of the Medical and Nursing Professions.

COW & GATE FEEDERS



Cow & Gate Milk Food



"Cow's milk made safe and suitable for baby"

It is said that Cow & Gate has saved more baby lives than any other preparation in the world

© COW & GATE LTD, GUILDFORD SURREY.

DURING PREGNANCY

IN the preparation for motherhood  be the patient a young primigravida  or an experienced multigravida  slim and delicate  or generously built  besides the routine tests  among your urgent instructions  will be

"Regular bowel movements daily." That will prevent many a headache, feeling of lassitude, and perhaps hæmorrhoids in the later months. You can prescribe AGAROL safely, because it exerts no effect upon the uterus nor does it interfere with lactation. Besides it is easily taken because it is palatable without artificial flavouring.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

A supply gladly sent for trial.

WITH SUPPLEMENT

No. 3695 SATURDAY, OCTOBER 31, 1931 Price 1/3

Trade "Pitibulin" Mark

Denotes Unvarying Pituitary Extract

Conforming to the requirements of the Therapeutic Substances Regulations, 1927, "Pitibulin" is prepared according to the official standards, its activity being expressed in terms of the accepted unit.

"Pitibulin" maintains the stringently high criteria of therapeutic efficiency, safety in use and stability, self-imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians.

It has made a reputation among the Profession as the Pituitary Extract which can be relied on in emergency.

"Pitibulin" is supplied in boxes of 6 and 12 ampoules containing 2·5, 5 and 10 units per ampoule.

Literature giving fuller particulars of the therapeutic applications of "Pitibulin" will be sent on request.

Just Issued

STEVENS'

New (3rd) Edition

Practice of Medicine

The great amount of new material which had to be incorporated in the NEW (3RD) EDITION—just ready—made it necessary to reset the entire book. In doing so Dr. Stevens embraced the opportunity of revising every line, deleting obsolete material, rewriting whole sections to make this new edition reflect Medicine as it is practised to-day.

NEW SUBJECTS

Psittacosis
Toxoid prophylaxis of diphtheria
Immunization to scarlet fever
Immunization to measles
Antitoxin treatment of erysipelas
Acute polyneuronitis
Vaccinal encephalitis
Chronic duodenal stasis and obstruction
Massive collapse of lung
Hypoglycemia of endogenous origin
Hyperparathyroidism
Hypoparathyroidism
Lipoid-cell splenomegaly of Niemann Pick
Spontaneous subarachnoid hemorrhage
Family and hereditary atrophy of optic nerve

REWRITTEN

Jaundice
Chronic cholecystitis
Acute pancreatitis
Chronic ulcerative colitis
Idiopathic dilatation of colon
Agranulocytic angina
Creatinuria
Lipoid nephrosis
Pernicious anemia
Sickle-cell anemia
Acute leukemia
Hodgkin's disease
Erythremia
Gaucher's disease
Banti's disease
Treatment of bronchiectasis
Essential arterial hypertension
Thrombo-angiitis obliterans
Occlusion of coronary arteries
Congenital heart disease
Sclerodermia
Prickets
Pellagra
Sprue
Thyroiditis
Hypopituitarism
Disseminated sclerosis
Osteitis fibrosa cystica
Undulant fever
Treatment of amebic dysentery
Verruca peruana
Glandular fever
Milk sickness
Coccidioidal granuloma
Treatment of uncinariasis

Octavo of 1,150 pages, illustrated By A. A. STEVENS, M.D., Professor of Applied Therapeutics, University of Pennsylvania Cloth, 35s net

Da Costa's Modern Surgery

NEW (10th) EDITION

"Wide and discriminate reading, evincing the most ample knowledge of the literature of his subject, a scrupulous fairness in appraising other men's ideas and methods, a transparent honesty, and complete absence of dogmatism, are the most attractive features of this book."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

By J. CHALMERS DA COSTA, M.D., Professor of Surgery, Jefferson Medical College, Philadelphia. Tenth Edition, Just Issued Octavo of 1,404 pages, with 1,050 illustrations, some in colours Cloth, 45s net

Boyd's Surgical Pathology

NEW (2nd) EDITION

"Accurate, clear, and well illustrated. An unusual but commendable feature for a book on pathology is the summary of symptoms which accompanies many descriptions, thus providing a link between the laboratory and the clinical sides. The book is well described by Dr. J. B. Mayo as a sincere attempt to place pathology before the student and practitioner from the practical standpoint."—BRITISH MEDICAL JOURNAL.

By WILLIAM BOYD, M.D., M.R.C.P.Ed., F.R.S.Can., Professor of Pathology, University of Manitoba. Octavo of 933 pages, with 476 illustrations and 15 coloured plates New (2nd) Edition Cloth, 42s net

Howell's Physiology

NEW (11th) EDITION

It is an encouraging sign of the times that a text-book so remote from any approach to the cram-book should have gained so much popularity with the medical student. The author has succeeded in making his subject-matter interesting and in many parts fascinating—an art deplorably rare in physiological writings. The book inspires respect rather than criticism.
—EDINBURGH MEDICAL JOURNAL

By WILLIAM H. HOWELL, M.D., Ph.D., Professor of Physiology, Johns Hopkins University, Baltimore Octavo of 1,099 pages, illustrated Eleventh Edition Cloth, 30s net

MacCallum's Pathology

FOURTH EDITION

"No doubt this book has often been taken down from the laboratory shelf to verify some small point, not to be replaced immediately the information sought has been obtained, it is apt to beguile the reader, enticing him to some stimulating thought. It teaches ideas rather than facts."—BRITISH MEDICAL JOURNAL

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University Octavo of 1,177 pages, 606 original illustrations, 50 in colours Fourth Edition Cloth, 45s net

The "HUE" Fire

The "Hue" fire is a constant money-saver in any apartment. Designed for scientific combustion it gives an amazing amount of heat, with a saving of not less than 33 1/3 per cent in fuel. A "Hue" fire can be attached to your old type stove in a few minutes and will burn efficiently with cheap coal and cinders. Prices from 12/-, according to size and finish.

The "TOILEX" Cabinet

For a quick and constant supply of hot and cold washing water in the Surgery, the "Toilex" Enclosed Cabinet is the ideal installation. The "Toilex" satisfies perfectly the demand for a handy Lavatory Basin for use after dealing with certain cases, and at the same time possesses the tremendous advantage of being out of sight when not required; the top closing down and forming a very convenient table. Only very simple plumbing is required to fit it. Price £11, delivered free within 50 miles.

May we send illustrated literature showing the full range of "Hue" Fires and "Hue" "Toilex" Cabinets.

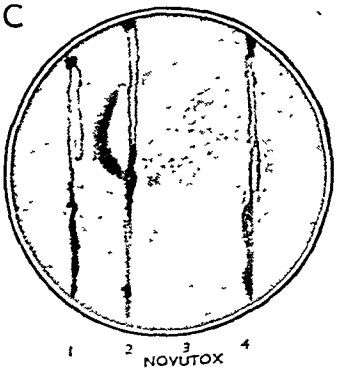
THE NEW LOCAL ANÆSTHETIC

self-sterilizing

'NOVUTOX' Local Anæsthetic is a radical departure in local anæsthetisia. Extensive clinical tests over a number of years have demonstrated that it is the ideal local anæsthetic. From every point of view it offers advantages over every known alternative. 'Novutox' Local Anæsthetic is autogenously sterile—and actually remains sterile for weeks after an ampoule is opened. It is seven times *less* toxic than cocaine. It can be used even when tissues are inflamed. After-pains and swelling are of rare occurrence even in extreme cases. Healing is quicker and cleaner after 'Novutox' Local Anæsthetic has been used.



Can be safely injected into infected infiltrated areas

NOVUTOX BRAND

LOCAL ANÆSTHETIC

BACTERICIDAL ACTION OF NOVUTOX. Novutox Local Anæsthetic and three other well-known anæsthetics (5 c.c. of each) were inoculated to a slight turbidity with Staphylococcus aureus. After one hour's action a platinum loopful of each was smeared on to a blood agar-agar slab.

In Solutions 1, 2 and 4, as shown in the illustration, the bacteria continued to grow, at a temperature of 37° C. in the incubator; whereas in Solution 3, the NOVUTOX SOLUTION, the bacteria were killed, and produced no growth, as can be plainly seen in the illustration.

Prices direct or through usual wholesaler. Large free testing sample on request

SURGICAL BELTS ALONE DEAL WITH THE ROOT CAUSES OF INTERNAL DISPLACEMENTS

The mechanical engineering of the abdomen in cases of internal displacement is now the first concern of patient and physician. X-ray photographs reveal irrefutably that aperients and intestinal antiseptics are futile in such cases. The long and frequently disappointing records of surgical intervention of a formidable and dangerous kind, show clearly how little this form of treatment achieves. The medical profession is beginning to realise that the surgical belt—giving upward support—can alone deal successfully with the root cause of mankind's tendency to sag—the downward pull of gravitation.

Domen surgical belts are constructed to give ample upward support from the only anatomically legitimate foundation—the pelvis. And they do this without harmful pressure—without embarrassment to the patient. Domen belts are designed for specific complaints and are strong, durable and light. Full information will be sent on receiving your card or a telephoned request.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

THE DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

Has the Ordinary Diet Sufficient Vitamin B?

Laboratory Reports on Bemax and Clinical Sample for personal trial will be sent to any Medical Man on request.

At the request of many correspondents a series of tests were recently conducted at the Bemax laboratories to determine how far the ordinary daily diet is an adequate source of Vitamin B.

The diet chosen for the tests included Eggs, Bacon, Bread, Butter, Beefsteak, Cabbage, Potatoes, Cheese, and a suitable percentage of A and D Vitamin.

The results prove conclusively that such a diet is in fact deficient in B Vitamin and cannot, by itself, meet the nutritional requirements of adults or promote normal growth in children.

Ample evidence is already available to show that partial B Vitamin deficiency results in a progressive deterioration of the digestive system, and may well be the principal cause of the many intestinal complaints which are so common to-day.

Bemax provides an ideal way of supplementing the ordinary diet with an adequate supply of B Vitamin, of which it is the richest known source in B_1, B_{11}, and B_{111}.

Its value as a tonic restorative food can hardly be over-estimated and its use has been attended with striking results in Dyspepsia, Constipation, Sleeplessness, Nervous Debility, Rheumatism, and all B deficiency diseases. As its content of E Vitamin is also exceptionally high it can be used with great advantage in the treatment of Sterility.

Medical Men are invited to write for reports of the tests referred to in this advertisement.

IN NEURASTHENIA.

Every potential neurasthenic is greatly assisted by liberal drinking of "Ovaltine." It is recommended as a between meals beverage or as a mid-day "light lunch," and it displaces tea or coffee with complete advantage.

"Ovaltine" is also invaluable when taken at the hour of sleep Its use in this way has often avoided the need for employing hypnotic drugs.

The value of "Ovaltine" has been proved many times in such cases. It provides nourishment of the right kind, and in a form readily dealt with by the impaired digestive organs "Ovaltine" permits of the liberal ingestion of food without taxing the digestive power.

"Ovaltine" is a complete natural food, yielding in one cupful a greater food value than three eggs. This delicious beverage is unquestionably a tonic nerve nutrient of a high order

REINFORCED COD LIVER OIL
—BOOTS—

THE therapeutic value of Cod Liver Oil is fully appreciated by the medical profession. It is recognised for its specific action (due to its high content of Vitamins A and D) in Rickets, Affections of the Chest, and diseases arising out of Malnutrition. Reinforced Cod Liver Oil—Boots is a biologically controlled preparation containing five times the normal amount of Vitamin D in addition to the normal amount of Vitamin A. The advantage of a concentrated oil needing only a fifth of the usual dose will be appreciated. Four fluid ounces of Reinforced Cod Liver Oil—Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil.

In 4-oz. bottles, 2/6

IN HÆMORRHOIDS

Operation May be Necessary

ANUSOL

★ ★ ★ ★ In the early stages, medical treatment may result in a cure. During pregnancy, in nephritis, diseases of the liver, operation may be temporarily inadvisable.

Quite often operation will be necessary for permanent relief. In the meantime, much can be done to alleviate pain, reduce congestion and control hæmorrhage, by using Anusol Brand Hæmorrhoidal Suppositories. No opiate or local anæsthetic to dull the pain sensation and obscure the symptoms.

After the operation, Anusol Brand Suppositories soothe and protect the mucous membrane, reduce congestion, relieve pain and itching, promote healing.

Before operation and after, Anusol Brand Suppositories have a well-defined place in treatment. Let us send you a trial supply for use immediately after examination in your consulting room.

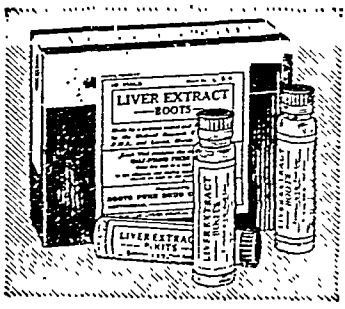
HORLICK'S

HORLICK'S MALTED MILK is as popular with the Medical Profession to-day as at any time during its history of half a century. It is a pure, clean, modified milk-food which keeps indefinitely and in any climate. Its cream-like consistency, its palatability, and its ease of digestion and assimilation, make it a safe, bland and soothing diet. Combining the nutritive qualities of pure fresh milk and the soluble extracts of malted barley and wheat, Horlick's is as valuable in infancy as in old age, in illness as in health. The Horlick process conserves the vital qualities of the constituent food materials and at the same time destroys pathogenic organisms. As a substitute for an ordinary milk diet Horlick's safeguards against outbreaks of typhoid and other fevers, septic sore throats, dysentery and other milk-borne diseases. To ensure the benefits of fresh milk without any of its dangers—prescribe Horlick's, hot or cold. Horlick's Malted Milk Co., Ltd., Slough, Bucks.



THE VITAMIN B_1 CONTENT OF LIVER EXTRACT

"The results suggest that those liver extracts which are rich in B_1 as well as in B_2 should be included in the list of medicaments available for use in cases in which administration of the vitamin B complex is indicated. Clinical evidence can indeed be adduced that such extracts are of practical value as general tonics, a fact which may be partly attributable to their vitamin content."

Extract from "The Lancet," June 27th, 1931, pp. 1423 and 1424.

LIVER EXTRACT (BOOTS) has been proved to be rich in both Vitamin B_1 and Vitamin B_2.

Then and Now

1903

"It is unlikely that starch will form a suitable food for young infants."*

1930

"Young infants even as early as the third month will digest appreciable quantities of starch perfectly."†

The paramount importance of starch in infant feeding at a very early stage is generally admitted to-day. Leading practitioners are occupied with the question of the best and most digestible form in which it can be administered.

There is a consensus of opinion in favour of wheat as opposed to oats as a first solid diet, both because its carbohydrate is known to be better tolerated and less rachitogenic than that of oats, and because it has greater digestibility and energy value.

During 1930, a leading biochemical society proved by careful experiment that "Cream of Wheat" was superior to oatmeal. After 4 hours the digestion of oatmeal was almost at a standstill, while that of "Cream of Wheat" continued at a scarcely diminished level for another 4 hours. When digestion was complete, the sugar yield from "Cream of Wheat" was 50% greater, and productive therefore of 1½ times as much energy.

As a first solid diet, as a food for children suffering from indigestion or intolerance of fat, and as a post-operative diet for adults, "Cream of Wheat" can be confidently given.

On receipt of your professional card, Dept W 11, Farr & Johnson, Ltd., 86, Clerkenwell Road, London, E.C.1, we shall be glad to send you a sample of "Cream of Wheat," and fuller details of the above-mentioned tests.

* Written statement by a leading authority on Infant Feeding.

† "*Infant Feeding*," by Clifford G. Grulee, A.M., M.D., LL.D. (J. & A. Churchill)

Marked Superiority

From all quarters there is an appeal to the public to assist the country in the present emergency by demanding the products of British labour, so that we do not import one shilling's worth of goods more than is necessary.

NATIONAL MARK MALT EXTRACT WITH COD-LIVER OIL is manufactured from the finest home-grown barley and pure cod-liver oil on premises subject to Government inspection.

It is guaranteed to be of a uniformly high standard of quality and of standardised content in its principal constituents. It must contain not less than 5% soluble protein, be of at least 1.4 specific gravity, thereby ensuring a high proportion of carbohydrates, include 15% cod-liver oil and have as a minimum 25 Lintner diastatic activity, thus conserving the valuable accessory food factors.

It is certain to give satisfaction and to offer the best value for money.

National Mark Malt Extract is markedly superior to cheaper imported brands of malt extract with varying constituents which make accurate prescription impossible.

National Mark commodities are nationally advertised and widely recognised as home produce of dependable quality.

Local Anaesthesia in Surgical Practice

REDUCTION OF FRACTURES

Typical Case.

T. D. A., female, aged 12 years.

Diagnosis: Fracture of Femur, malunion, malposition.

Operation: Reduction with Gratton osteoclast seven weeks after injury.

Anaesthesia: Local infiltration block 7 cm. above the point of fracture; 90 c.c. of 0.5 per cent. Novocain-Adrenaline solution were used. The child's limb was small, and therefore but a moderate amount of solution was required. The thigh was heavily padded with felt, and the Gratton instrument applied. The bone was refractured and the result checked up by roentgenograms before the removal of the Gratton instrument. This child had no pain at the point of fracture, but complained moderately of the stretching of the muscle, which gave some distress in the region of the knee-joint. However, the anaesthesia was entirely satisfactory, and the child partook of a hearty meal while the plaster cast was being trimmed.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

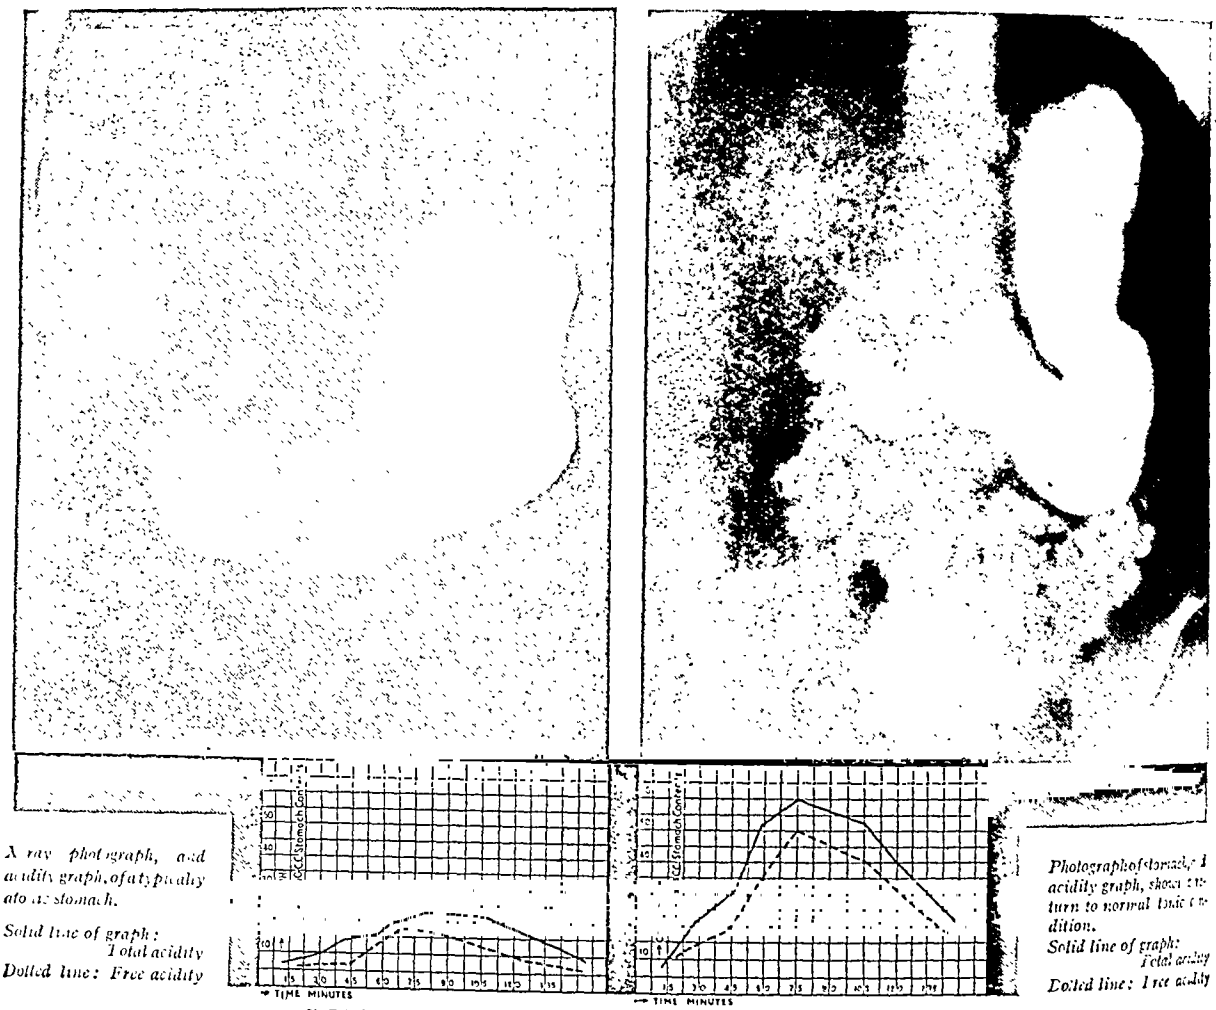
Nutritional anaemia in infancy

IT has recently been shown that breast milk does not contain an adequate amount of iron and that from the early days of infancy it is necessary to supply iron to the organism, if healthy development of the child is to be attained.

The organic iron in Virol from Glycerine Extract of Red Bone Marrow and from yolk of eggs is absorbed with ease.

The vitamin-containing Fats are very finely emulsified; they are, therefore, easily digested by the most sensitive alimentary tract at all ages, including earliest infancy.



All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure.

X-RAY PHOTOGRAPHS BY COURTESY OF KODAK MEDICAL LIBRARY

X-Ray tests confirm

the tonic value of appropriate stimulation

A MEDICAL INVESTIGATION shows 99 out of every 100 doctors recently interviewed are recommending Brand's Essences of Beef or Chicken during the early stages of convalescence: these essences are valuably tonic, they prepare an atonic stomach to accept and digest more solid diet....

Radiology has recently thrown much light on this whole field of atonicity. Brilliant X-ray studies have revealed the amazingly quick return to normal stomach tone made possible by appropriate stimulation, even in cases showing very advanced atonic symptoms. Acidity curves plotted at the same time run parallel, showing equally rapid return of normal gastric flow.

For over a century the medical profession of Great Britain have used Brand's Essences of Beef or Chicken in dealing with atonic conditions. Radiology now confirms this; doctors are finding these essences especially valuable in all cases of internal disturbances; in states of exhaustion with recovery hampered by anorexia; in the post-influenzal state; in specific fevers and disorders associated with pyrexia.

Only the pure juices of finest freshly-killed English meats are used, without preservatives of any kind. This means considerably greater nourishment, as well as purity. Brand's Essences supply actually eight times the usual nourishment of products of this kind. Samples sent on receipt of a professional card. Dept. F42. Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

THE EARLIEST EXTANT REPRESENTATION OF WAYLAND THE SMITH, HERO OF ONE OF THE EARLY LEGENDS OF THE TEUTONIC PEOPLE.—Wayland was the son of a giant sailor and a mermaid. He became a cunning smith, learning his art from MIME and from the dwarfs. With his sword, Miming, one of the wondrous swords of Teutonic legend, he overcame in contest the smith Amilias at the court of the king. This monarch set up Wayland in a smithy, upon an island near his castle, after cutting the sinews of his knees in order to prevent him from leaving his service. To avenge himself, Wayland slew the king's two sons and then escaped. He fashioned the skulls of these sons into drinking cups. This incident is here depicted. Wayland is seen holding one of the skulls in a pair of tongs over the anvil. On the ground lies a headless body. In front is the king's daughter, who has come with an attendant to have a ring mended. The scene is represented upon the front of a casket of carved whalebone, which is a most interesting piece of Northumbrian work.

'Just as Vitamin D holds the key to the formation of teeth and bones so Vitamin A controls the structure of some epithelial tissues. . . .'

(Report of Hastings Lecture, Supplement, B.M.J., March 21st, 1931, p. 85)

RADIOSTOL
Standardised
Vitamin D

THE recent report on *'The influence of diet on caries in children's teeth'* by the Medical Research Council demonstrates that the onset and spread of dental caries in children can be controlled by the addition of Radiostol to the normal diet. The report states further that ***'the successful research . . . in this field points to immediate and widespread measures of preventive control'.***

Radiostol Solution for such preventive measures ***—exactly identical with that used in the investigation—*** is available to any physician from the principal pharmacists.

RADIOSTOLEUM
Standardised
Vitamins A & D

In a recent investigation on the anti-infective action of Vitamin A (B.M.J., Oct. 3rd, 1931, 595) Radiostoleum was administered to 275 women during the later weeks of pregnancy whilst another 275 were kept as controls; it was found that only 1·1 per cent of the treated cases as against 4·7 per cent of the controls developed infection (B.M.A. standard of morbidity), ***thus showing less than one-fourth the susceptibility to infection when Radiostoleum is administered.***
Similar remarkable results of a smaller-scale experiment with Radiostoleum were reported previously (B.M.J., June 1st, 1929, 984).

AVOLEUM
Standardised
Vitamin A

The anti-infective Vitamin A is available also through the medium of Avoleum—a highly-concentrated standardised liquid preparation of Vitamin A without the admixture of Vitamin D. Whilst Radiostoleum is recommended for administration to children and to pregnant and lactating women, Avoleum is more suitable for elderly patients and for cases in which the calcifying Vitamin D is contra-indicated.

Remarks
ON
THE PROBLEM OF THE CHILD IN THE TUBERCULOUS HOUSEHOLD*

BY
R. C. WINGFIELD, B.A., M.B., B.Ch. (Oxon), F.R.C.P.,
MEDICAL SUPERINTENDENT, BROMPTON HOSPITAL SANATORIUM, FRIMLEY, SURREY

Research on the problem of tuberculosis in childhood is a great feature of present-day activities. Facts and figures are pouring in from every civilized country. It might almost seem that the tuberculosis of adults was being neglected and that the best of our attention was being directed to childhood tuberculosis. I think this is in some degree true, and the reason for it is that there is a hazy idea in the air that in the prevention and treatment of childhood tuberculosis lies the key to the problem of the prevention of the disease in adults. This may or may not be true. It is, however, important to realize that the researches on tuberculosis in childhood are not finished; they are hardly started indeed, the results therefrom are as yet but partially digested, and the truths that they seem to show to-day may be profoundly modified as further knowledge is acquired.

The treatment and prevention of adult tuberculosis has been undertaken as a national duty, and Sir Robert Philip, one of the fathers of the movement, in his Malcolm Morris Memorial Lecture claims that the rapid decrease in the mortality from the disease may be ascribed to the work of this movement. His statement may meet with criticism, but no one can deny that the decrease has at any rate accelerated with the movement. Such a national duty involves the tax-payer, through the State, in great expense, and if it is to be enlarged and intensified in the direction of our childhood population, as Sir Robert Philip suggests, this expense must increase.

In addition to the financial burden public health regulations will follow, and laws which are bound to affect the liberties and perhaps the happiness of the individual, both child and adult. Neither financial responsibility nor wise law-giving must be shirked if these are going to be of real benefit to the community, but they must be founded upon *real truths and not upon hasty conclusion. In the mean*while, before any national movement is made, if it is made at all, the general practitioner and the public health official are still day by day confronted with the problem of the child in the tuberculous household; and from the way in which this problem is being tackled, or ignored, in different countries and in different parts of the same country, it would seem that the profession is wandering in the dusk of a thick forest of conflicting opinions, along ill-made tracks where signposts are lacking or else are vague and inaccurate. This is my excuse for opening this discussion. I shall endeavour to give a survey of the facts that seem to have emerged from research up to the present. I have exercised my discretion in picking and choosing, for not all that is printed is worthy of blind acceptance, but I have tried to be unbiased. To this I shall add some constructive ideas on our possible future policy. I expect, and hope, that both my conclusions and my suggestions will meet with fierce and searching criticism, which may winnow away the chaff of inaccuracy and false perception and leave behind perhaps a few grains of real truth.

The profession must approach this problem from two angles—that of clinical medicine and that of preventive medicine. They are two very different view-points and not always harmonious. The clinician's main goal is the welfare of his individual patient, and if he wholeheartedly presses towards that goal he may not see eye to eye with the public health official, whose duty is rather to ignore the individual in his striving for the good health of the community. And since the problem of the child in the tuberculous household is both a clinical and a public health one, it must be approached from both angles; but any conclusions that are drawn, or any suggestions that are made, must satisfy the clinical conscience of the general practitioner and the preventive-medicine conscience of the public official.

I will bring the problem, as I see it, before you in a series of questions. I will endeavour to extract what I think are the true answers to those questions from the works of those who are researching on tuberculosis among children, and finally I will discuss the methods that have been or might be adopted as a result. In order to avoid *the repetition of the rather clumsy phrase "the child in* the tuberculous household," I shall refer to these throughout this paper as "contact" or "exposed" children.

Four Questions

The problem appears to me to be contained in four questions:

1. What is the relation of the incidence of infection, in time and intensity, among contact children to that among the general child population?
2. Does the contact child run greater risks of immediate sickness or death from tuberculosis than the average child?
3. Is the contact child exposed to greater risk of future sickness or death from tuberculosis than the average child?
4. Does the contact child constitute an immediate danger to the community?

I think that if we can find satisfactory answers to these questions we shall know the limits of the task before us.

What is the relation of the incidence of infection, in time and intensity, among contact children to that among the general child population?

In answering this question we find ourselves on fairly certain ground. For the purpose of our present discussion the end of the fifteenth year is taken as the limit of childhood. It is now universally agreed that, for practical purposes, the presence of skin sensitiveness to tuberculin is a proof of infection, and that a positive reaction means that somewhere in the body is a focus of tuberculosis, dormant and non-progressive perhaps, and living tubercle bacilli. It would seem possible that the lesions in question may be quite healed, since it has been shown by McPhedran and others that by annual inoculation living tubercle bacilli can be found in the tissues surrounding completely calcified lung foci and around fibrous apical scars in as many as 24 per cent. of the cases examined. In certain circumstances there may be no skin sensitiveness in infected subjects—for instance, in the later stages of acute and progressive tuberculosis, and during acute intercurrent diseases such as measles. But these exceptions are comparatively rare, and when dealing with large numbers of children, the skin reaction can be used as definite evidence of the presence or absence of infection.

The pioneer work in skin sensitiveness is associated with the name of von Pirquet and his scarification method. I think, however, I may safely state that his method has been superseded by the intracutaneous method of Mantoux by which 0.1 c.cm. of various dilutions of old tuberculin are injected into the skin. Von Pirquet's method is still used and upheld by some workers, but I will not weary you with the literature and figures contrasting the two methods, and simply refer you to Report No. 2 of the Brompton Hospital Research Department.

What is the incidence of infection among the average child population? This is an infinitely variable figure,

* Read in opening a discussion in the Section of Public Health (including Tuberculosis and Occupational Diseases) at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

depending apparently on locality, general and tuberculosis mortality rates, race, and social environment. The highest known figures are those of Hamburger and Monti for Vienna, showing 94 per cent. infected at the age of fifteen, closely followed by Hetherington and others with 81 per cent. for Philadelphia. At the other end of the scale come Taylor's figures from Iowa with 31 per cent. infected at fifteen years of age. Heimbeck on 786 children between five and fifteen gives only 23 per cent., but he has used the Von Pirquet method. No. 2 Report of the Brompton Hospital Research Department gives the incidence of 1,000 children of the London working-class population of 59 per cent. infected at the age of fifteen. This may be taken as a fair average for that locality, but from the variations seen in the different parts of America it is probable that this figure might vary by 15 or 20 per cent. either way in different localities in England.

Contact children show a much higher incidence. As this is a definitely ascertained fact, I will quote only two examples. Opie for the Philadelphia district gives at the age of fifteen: Contact children 90 per cent. infected, non-contact children 64 per cent. The Brompton Research Department No. 2 Report gives: (1) average of all children, contact and non-contact, at the age of fifteen 59 per cent. infected; (2) non-contact children 52 per cent. infected; (3) contact children 82 per cent. infected. These figures speak for themselves, but analysis brings out another important fact. The figures show that by the age of fifteen the incidence is much higher among contact children, but closer investigation reveals that while in non-contact children the incidence increases steadily year by year from birth, in contact children the incidence reaches almost to its summit at a much earlier age. To quote Opie again, at the age of two and a half years among contact children 78 per cent. were infected, a figure very close to the 90 per cent. at fifteen. Among non-contact children 22 per cent. were infected, a figure far below the 64 per cent. at fifteen. The Brompton figures disclose the same, as this table shows:

Age.	Contact.	Non-contact.	All Cases.
	Per cent.	Per cent.	Per cent.
0—5	67	17	25
5—10	77	31	39
10—15	82	52	59

Therefore we may answer our first question by saying that although the incidence of infection is high among the general child population and varies in different localities, the incidence among contact children is much higher and the infection takes place much earlier, almost reaching its highest point during the first five years of life.

Does the contact child run greater risks of immediate sickness or death from tuberculosis than the average child?

Here again we can get a definite answer to our question. The death rate from tuberculosis, and therefore presumably the incidence of clinically recognizable tuberculosis, is definitely higher among contact children than among non-contact. Every investigator from every country agrees on this main point. But that is the only agreement they do reach. The actual figures produced are amazingly variable, and I do not propose to quote them. Some of the Continental figures indicate such a terrible mortality among contact children that one can only hope that they are incorrect. From our own country we have the evidence of Lissant Cox and others in Lancashire, with an experience of 1,486 children, and the Brompton Hospital Research Department Report No. 1 with an experience of 1,192 children of the London working-class population. Both these investigations show a definitely higher mortality from tuberculosis among contact children, but that as compared with the Continental figures the increase is small. This statement needs qualification. It appears, though it is difficult to get accurate figures to prove it, that the risk of death is not equal through all the years of childhood but that it is much greater in infancy, that is to say, up to the age of three. Smellie, in the *Birmingham Medical Review*, quoted by Dixon, shows that the highest mortality in that district is between the ages of one and two years, and Opie and many others have stressed the danger to life of an infection in a child under one.

Those who have given thought to this aspect, notably, among others, Myers of Lymanhurst, are emphatic that the danger lies not in infection, but in continuous infection when the effect of a non-lethal dose may be magnified by being received during the negative phase following a previous infection. Leroy Gardiner's work, published in the *American Review of Tuberculosis*, October, 1930, shows that after a first infection the negative phase probably lasts for at least fifteen days, and from four to six days after subsequent infections. I feel that the foundation of the doctrine of the danger of continuous exposure is probably sound. This would explain the higher mortality and greater risks of infancy, which is a time of more intimate contact with infected parents.

The cause of death is mainly, of course, generalized tuberculosis with meningitis. Smellie gives as the causes of death from tuberculosis in children: Cerebral tuberculosis 51 per cent., abdominal tuberculosis 33, pulmonary tuberculosis 14. The freedom of contact children from pulmonary tuberculosis is further suggested by Agassiz, who states that of 134 children under his care with pure pulmonary tuberculosis, in under 50 per cent. could evidence of direct contact be procured.

Although it has been stated that infection in an infant implies a bad prognosis, Myers, in support of the doctrine of the danger of continuous exposure, says that the prognosis is not bad; he presumably means if the infant is protected from future exposure after the first infection.

We may then sum up our answer to the second question by saying that the contact child is exposed to definitely greater risk of illness and death from tuberculosis than the average child, that the younger the child the greater the risk, and that it is suggested that the danger is due to repeated infections.

Is the contact child exposed to greater risk of future sickness or death from tuberculosis than the average child?

Here we get on to more debatable ground. The surest way to arrive at an answer would be by a "follow up" of a large number of contact children and noting the incidence of and mortality from tuberculosis among them as compared with the general population. This would be a stupendous task, as it would have to cover two generations of research workers and even then might be misleading, since the "followed up" children would certainly be more carefully supervised than the average child. As far as I know no such investigation has ever been attempted. We must try to get at it another way. Among 500 consecutive adult patients passing through the Brompton Hospital Sanatorium at Frimley a history of direct contact could only be obtained in 2.5 per cent. There is every chance of inaccuracy in such an enumeration, and even assuming that the figures are 100 per cent. inaccurate, they would still suggest that childhood contact, so far from being a menace as regards adult disease, may even exert some protective influence. Turning to pulmonary tuberculosis among adolescents, Dr. Lloyd has told me that among 208 consecutive cases of pulmonary tuberculosis in patients between the ages of fifteen and twenty he found 31.5 per cent. who had direct childhood exposure, a much higher figure than that for the adult cases. But against this we have a statement by Dr. Lissant Cox that during a certain period not more than 1 per cent. of the cases

pulmonary tuberculosis between the ages of fifteen and enty-five in Lancashire had been sent to the dispenies in childhood for previous examination. When we nsider the careful way in which contact work is done Lancashire, this can only mean that very few of these olescent cases had direct childhood exposure.

The problem is a very difficult one. We must at all costs oid suppositions and assertions, and confine ourselves facts. For instance, Rathburn, quoted by Myers, states at 4 per cent. of those with the childhood type of pulnary tuberculosis furnish 75 per cent. of the adult type pulmonary tuberculosis of adolescents. I do not know what he bases these exact figures, and certainly Dr. yd's figures might seem to support him. But until are certain, such statements are dangerous and must nder progress.

Opie tells us that by twenty years of age 100 per cent. the population where he has worked are infected, and e figure generally is certainly high. It is also certain at previous infection is necessary in any patient who ffers from the adult type of chronic pulmonary tuberlosis, but we have no evidence as yet that direct exposure childhood in any way influences the incidence of pulnary tuberculosis among adults.

Passing from the question of childhood exposure to the estion of childhood infection, it is quite certain that a rvived infection does carry with it a certain amount of ture protection. This is beautifully demonstrated by me figures of Heimbeck. Of the nurses who were cruited to the tuberculosis hospital at Oslo between 1924 d 1928, 48 per cent. had been previously infected, as own by a positive von Pirquet reaction, and 52 per cent. d a negative von Pirquet reaction (his figures might ve been different if the Mantoux reaction had been used), d of 337 nurses in residence, of whom 152 were nonactors, 53 developed clinical tuberculosis during their aining, and of these no fewer than 51 came from the nonactor class.

Therefore, the only answer we can give to our question that childhood infection does exert a protective inence, but that there is no evidence to show that the tremely early infection, which is the feature of childod exposure, exerts any influence on the incidence of lult disease.

Does the contact child constitute an immediate danger the community?

Our knowledge of the exact vehicles for the transference f the tubercle bacillus from person to person is somewhat agmentary. Calmette suggests that in any infected inividual tubercle bacilli are excreted by the bile. It has lso been demonstrated that there are non-acid-fast forms f the tubercle bacillus which still retain to the full their athogenicity. The possibility of filter-passing forms has lso been investigated. All these suggestions bear imortantly on the question of infectivity, but as long as hey remain in the realm of hypothesis we cannot use them o answer our further question. We must say that, as far s our own present knowledge goes, the contact child not uffering from clinical tuberculosis is not a public danger. Before we can say that they are carriers and spreaders of nfection we must wait for future research.

To sum up the position:

1. Tuberculosis infection is very common among children.
2. The incidence varies widely in different localities.
3. It is much higher among contact children.
4. It takes place earlier in life among contact children.
5. The mortality from tuberculosis is higher among contact children.
6. Infection is more dangerous to infants.
7. It is more dangerous if there is continuous exposure.
8. Childhood infection exerts a protective action as regards adult tuberculosis.
9. Infantile infection exerts no recognized influence on the incidence of adult tuberculosis.
10. The influence of infantile infection on the incidence of adolescent tuberculosis needs further investigation.
11. Contact children, as far as we know, do not constitute a public danger as spreaders of infection.

Constructive Suggestions

Now what constructive suggestions can be made on the basis of these postulates? I have never myself regarded the problem of the contact child to be so all-important from the preventive medicine point of view. Sir Robert Philip ascribes the decreasing mortality from tuberculosis at the present day to our active anti-tuberculosis legislation and activity, but tells us that we are concentrating too much on the pronounced lesions, notably pulmonary tuberculosis. But the decline in infant mortality during the past twenty years has been immeasurably greater than the fall in the general mortality, or than the fall in the mortality of any other age period; it has been more than twice as great. If the fall in the general death rate may be ascribed to our efforts, may not the greater fall in the infantile death rate be ascribed to them too? And may it not be that by tackling the problem of adult pulmonary tuberculosis, and by continuing to do so vigorously, we are making our strongest attack on infantile tuberculosis and tuberculosis as a whole?

But, however much we concentrate on adult tuberculosis, the problem of the child in the tuberculous household will still confront the general practitioner and the public health officer.

The general practitioner must view this mainly as a clinical problem; his duty is towards the child and its parents rather than to the community at large. Is he to examine all the contact children in his practice by the Mantoux reaction for evidence of infection and by the *x* ray for evidence of lesion? No, he should not have to deal with these personally; but these investigations should be made for him, and he should have a knowledge of their results. His duty is to watch, and to turn his attention to the proper hygiene of the home. The importance of this will be realized when we learn from Sir P. Varrier-Jones that there is a complete absence of clinical tuberculosis among 133 children born at the Papworth settlement. He must realize the danger not of exposure but of continuous exposure. That is to say, he must use every effort to sterilize the open case which is the source of contact, and to dilute the infection either by treatment or by segregation, partial or complete. Contact infants must be his especial care in this direction. He must teach the parent and the adult how by attention to a few simple hygienic rules they can minimize the danger to the children almost to the vanishing point. It is not his duty, and would be a waste of his time and injurious to his practice, if he were to say to the tuberculous mother, as did one practitioner of my acquaintance, "You must never see your child again." When the contact children of his practice reach adolescence, then is the time he must be most wise and wary. That is the time when the parent and child need guidance in choice of work, life, and environment. That is the time when the *x* ray will be particularly useful, for McPhedran has said (and he is a man to be listened to) that apical infiltration in childhood and adolescence, although apparently latent, always goes on to definite clinical pulmonary tuberculosis if untreated.

The public health officer will stand behind the practitioner to supply him with such facilities as will help him in dealing with this problem, or to step into the breach with these facilities in the interest of the patient if the practitioner or the parent is neglectful of his duties. I think that he will be wiser if he, too, views the problem from the clinical standpoint. For the answers to our questions fail to show that the contact child is an important public health problem. It will be the public health officer who will draw the attention of the general practitioner to open cases of tuberculosis which are the source of contact to the children in his practice. I would like to see a tuberculin reaction done on every child when it reaches a certain age. It certainly should be done on every contact child, and every positive contact reactor should have the thorax examined radiologically, and the information thus obtained should be filed and recorded for future information and research and should be passed on to the general practitioner. This is essentially the work of the specially trained public health officer. Further, he should be ready to re-examine such children whenever the practitioner thinks it is necessary, and be ready at all times with his special knowledge of the disease and with the facilities at his disposal to give any advice or help that may be required.

These suggestions on the attitude and the duty of the general practitioner and the public health officer toward the contact child may be well enough, but save for the plea for the more extensive use of tuberculin as a diagnostic agent and the x ray, they do not contain anything new. What can the results of present day research, as we have seen them, suggest in the way of improvement? We provide institutional accommodation for the definite case needing treatment. But what exactly is the definite case needing treatment? The boundary between infection and clinical disease is ill defined. Do we go near enough to that boundary in choosing our cases that need treatment? What types of lesions are likely to develop into clinical disease? The adolescent with open and obvious pulmonary tuberculosis is a pretty hopeless problem. If only we knew more about the danger signals, could we not avoid this catastrophe more often? These are, I think, some of the great gaps in our knowledge; and it is in this direction to-day that we need guidance, and in which future research should proceed.

If the answers to these questions are forthcoming, perhaps more cases will be found to have definite clinical disease and to be in need of treatment, institutional or otherwise. But how shall we deal with those who only need preventive treatment? The so-called preventorium is largely used in Canada and the United States, and perhaps we might make more use of it in England. But if we do it must be properly used. I quote from Dr. J. B. Hawes junior, writing in the *American Review of Tuberculosis* in July, 1929, about the Prendergast Preventorium; he says:

> As I study the results of 110 children discharged from our Preventorium I am more convinced than ever that the ultimate success of preventorium treatment depends upon *thorough, aggressive* and *prolonged* follow-up work. No child should ever be allowed to return to a home where it will again be exposed to infection. This should be an absolute rule.

This statement appears to me, if it is a true conclusion, to show that a preventorium is absolutely useless, at any rate as it is conducted in that district. The expense and trouble of such an institution might be saved and, to use Dr. Hawes's words, a *thorough, aggressive* and *prolonged* Grancher system might be substituted instead, or the rigorous enforcement of some such harsh law as they have in Chicago forbidding children to live in the same house as an open case of tuberculosis. No, it does not seem that a limited course of institutional treatment on sanatorium lines can help the problem in any way. A preventorium that I saw in use in Toronto seems to meet the case better. There, contact children are placed, provided they show no evidence of active clinical tuberculosis, and kept and trained and taught until the tuberculosis authorities are satisfied that their home conditions have been rendered as satisfactory as possible. The average stay is three to four months. That seems a reasonable method of spending public time and money for the benefit of the contact child. In general, short courses of enforced hygienic life, and harsh interference with family liberty and happiness, do not appeal to me.

B.C.G. Immunization

Are we going to get help from immunizing processes? Is Calmette's B.C.G. the weapon of the future? No, we must deal very cautiously with B.C.G. It seems to arouse the controversial spirit. There are two questions to be answered. 1. Is it harmless? 2. Does it protect?

The answer to the first question is not certain yet, but we can say that for practical administration, if used according to the technique of Calmette and Guérin, it is harmless. The adverse reports and accusations of its toxic possibilities have come mainly from pure bacteriologists and laboratory investigations, and as far as I can see have no very great practical bearing. Does it protect? In cattle apparently yes, to a certain extent. I must confess that the French figures on the vaccination of children leave me confused and unimpressed, but I should like to quote Heimbeck again, this time on the protective power of B.C.G. Still dealing with the nurses coming to tuberculosis work in Oslo, he found:

> That of 322 non-reactors to tuberculin who were inoculated with B.C.G., 294 became reactors.
>
> In 1924 there were 8 cases of tuberculosis among non-reactors.
> In 1925 do. 25 do. do. do.
> In 1926 do. 14 do. do. do.
>
> In 1927-28 among 44 non-reactors who were vaccinated there were no cases of tuberculosis, and among 12 non-reactors who refused inoculation there were five cases.

He summarizes by saying that previous to 1927 the morbidity among non-reactors was 16 per cent., and in 1927 among vaccinated non-reactors 0 per cent. These are very striking figures. And it is to be noted that a very large percentage of the non-reactors became reactors after vaccination.

These figures do suggest that B.C.G. vaccination may be a useful weapon to tide over the dangerous period of infantile contact and exposure, in conjunction with other methods for preventing continuous exposure to massive infection. These other methods are necessary, for a first infection with ordinary tubercle bacilli or with B.C.G. will confer no immunity that can overcome a massive infection or continuous intense exposure.

Whatever protection is afforded by B.C.G. is admittedly short-lived, and continuous vaccination throughout childhood of all contact children is an impossibility, but re-use on infants might convert the unprotected non-reactor into the partially protected reactor. Myers has stated that in children a high degree of hypersensitiveness to tuberculin is a dangerous sign. This suggests, for those who cannot bring themselves to support the use of B.C.G., the use of the admittedly harmless tuberculin. It would be quite possible for those contacts who showed what was agreed to be a dangerous degree of hypersensitiveness to be desensitized by a course of tuberculin injections.

I repeat that I do not think the problem is so very easy a one as it sounds, and it *seems* to me that the future safety of our children depends on the improvement in

rsonal, familial, and community hygiene; and what stas of possibility are opened up by Professor Mellan- 's lecture on the prevention of disease by the correct eding of children It is obvious that we must not try escape infection for our children, for, dangerous though fection is, it does bring with it protection, and we must old the state of affairs that Heimbeck deplores in his vn country in these words

"Thanks to tuberculosis work, infection in the home is not common and is postponed until the individual goes out work Thus the endeavour to avoid tuberculosis infection childhood has resulted in the transference of a high mor- lity and mortality to just those years when the individual ould begin to work for society in return for what society s done for him in the matter of education in his earlier ars"

Really, it is Nature's problem She will find her own lution, and I think she is solving it, as Dudley Sheldon ggests when he says:

Morbidity equals infection pressure versus herd immunity erd immunity increases with the herd's past experience of the eternal cause of infectious disease, and although infection essure must be greater with the increase of urbanization, rd immunity outstrips it."

THE BROKEN NOSE*

BY

E WATSON-WILLIAMS, *M C*, Ch M

S R IN CHARGE, EAR, NOSE, AND THROAT DEPARTMENT, BRISTOL ROYAL INFIRMARY

(With Special Plate)

broken nose is common enough and regarded often, xcept perhaps by the victim, as matter for mirth rather han for sympathy Fortunately, even in these motoring ays, the majority of our cases are of a mild type when here is no subsequent external deformity, any distortion f the nasal septum can be readily dealt with by sub- mucous re ection Omitting those in which there was no nanifest displacement of the nasal bones, the etiology in wenty seven cases treated personally during the four nonths March to June, 1931, was as follows.

	Mild	Severe
Football	3	—
Cricket	4	—
Boxing etc	1	1
Motoring	2	4
Cycling	1	1*
Falls etc	3	1
No record	6	—
	20	7

* Collision with motor lorry

But the deformity resulting even in the milder cases may be very annoying—to a girl possibly really distressing If it is to be avoided it is important that treatment should be undertaken *early*, since the processes of repair lead to rapid absorption of bone edges, and callus formation may produce an unsightly bossing along the margin of the frontal process of the maxilla, so that a good result is often not obtained by late treatment, even though the bones be re fractured and set Still more important is it that treatment should be intelligent—that is, guided by a proper understanding of the exact nature of the deformity, and the best method of reduction Though it is often easy to see the line of fracture in an ordinary skiagram, the actual displacement in a mild case is not well shown unless resort is had to a stereogram Gross damage is, of course, sufficiently obvious in any good film (Figs 1 and 2 on Plate).

* A Bristol University Post-Graduate Lecture.

In a typical mild case the accident is followed immediately by epistaxis, and very soon by nasal swelling, internal and external, probably with a black eye in addition; it is impossible in these circumstances to estimate damage Local treatment is confined to suture of lacerations, etc In four to eight days the swelling has gone down, nasal obstruction is slight or absent, and one can make out the characteristic deformity (Fig 3 on Plate). The bony nose is bent definitely over to one side, the septum and tip being little affected. If now one attempts simply to push the nose back into place, in all but the most trivial cases this is found unexpectedly troublesome, and a symmetrical appearance is not achieved (Fig. 11) Also, the deformity tends obstinately to recur; internal splints effect nothing, while external splints or padding are often impossible to retain in place If the true mechanism of the fracture dislocation is appreciated, reduction is perfectly simple, and one can almost guarantee that there will be no subsequent deformity

The actual displacement of bone presents three features (Figs 9 and 10)

1 On the side from which the blow fell the lower two-thirds of the nasal bone, and often the anterior sharp margin of the frontal process of the maxilla, are displaced inward toward the mid-line, mainly by rotation round the posterior margin of the fragment as a hinge, with very little backward displacement

2. On the opposite side a corresponding piece of bone, or rather less, is displaced in the same direction—that is, outward—again hinging on its posterior margin

3 In the middle the first fragment has been driven in beneath the second It is lack of appreciation of this imbrication-impaction that is the source of difficulty and failure in reduction Figs 9 to 13 are diagrammatic sections at right angles to the plane of the nasal profile, to explain the common types of displacement and the steps in reduction

Treatment

A general anaesthetic is necessary, and oxygen ether will be found convenient Bleeding is usually slight; if desired, the nose may be lightly sprayed just before induction with 5 per cent cocaine solution and packed anteriorly with gauze wrung out of 1 in 10,000 adrenaline When anaesthesia is complete a post-nasal sponge can be introduced The only instrument needed is a strong forceps, the blades 2 to 2½ inches long and slightly bowed so that only the tips touch. Jansen's longest bone forceps may be used, the common septum forceps is too thick for most noses Before use the tips are well padded by winding on three or four turns of half-inch strapping

Operative Procedure

A.—Into the nostril of the side *toward which* the nose is bent pass one blade of the forceps, pushing it up until the other blade outside the nose is just over the nasal bone Grasp the bone firmly and twist it yet further outward, still round the posterior margin as an axis (Fig. 12). (This step is not always essential, but greatly facilitates disimpaction)

B—In exactly the same manner grasp the other or in-driven bone, and rotate it also well outward to a position corresponding with the first (Fig 13) Sometimes a slight lifting movement is required in addition

C—A finger placed externally can now feel that both bones are freely movable, and that there is a definite gap between them anteriorly With the finger mould the two bones symmetrically together, like the leaves of a double drawbridge, so that they lock in the mid line If necessary, the forceps may be used with one blade up each

nostril during this process to support the bones or to correct any anterior deviation of the septum. Once locked there is no tendency to displacement, and indeed considerable force may be needed for this; no splints are required, and the patient can return home forthwith. If during the ensuing week he thinks the nose is not quite symmetrical he may massage it forcibly into place with the thumb twice daily: this is rarely necessary. In this type of case there is seldom much alteration in the profile, and bilateral symmetry supplies the best test of treatment.

CASE I

Nose broken at football, leading to typical deformity of the simple type (Fig. 3 on Plate). The second photograph (Fig. 4 on Plate) shows the result four days after reduction by the method described, no splints being required.

When the violence has been great the problem is frequently less simple. In addition to laceration of the soft parts the bones may be comminuted and driven backward; the whole bridge of the nose may be knocked flat upright, bend each leg directly backward about half an inch above bend P (Fig. 16). Bend R: at R, two inches back from Q, or somewhat less, bend the wire up and then forward parallel and close to itself (Fig. 17). Bend S: at S, a point slightly in front of Q, bend the wire down at right angles, shaping it to the contour of the nasal profile in the region where support is wanted. Bend T: bend the wire backward at a point that will correspond to the upper part of the vestibule, and then again downward at T (Fig. 18). The distance T R = the distance Q R; S T is equal in length to the distance from the upper end of the fracture to the lower margin of the nasal aperture.

The splint is now ready for insertion. Pass the portion Q R S into the nose, one "leg" on each side of the septum, until the central part P Q presses firmly against the philtrum. With septum or other forceps hold the part Q R in close contact with the floor of the nose, and thrust the portion S T directly upward in the direction indicated by the arrow (Fig. 18); in doing this

TRANSVERSE SECTIONS THROUGH NASAL BONES AT RIGHT ANGLES TO LINE OF PROFILE

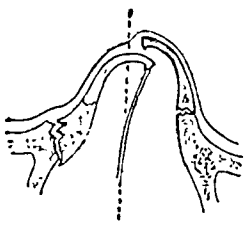

FIG. 9.—Typical "mild" deformity.

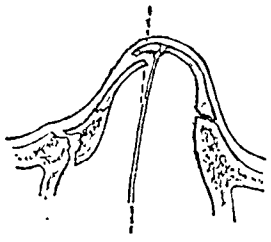

FIG. 10.—Another common type of fracture.

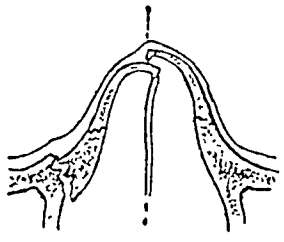

FIG. 11.—Result of replacement without disimpaction.

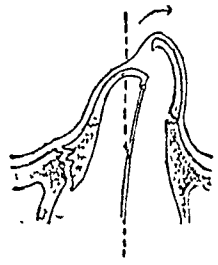

FIG. 12.—First movement of disimpaction.

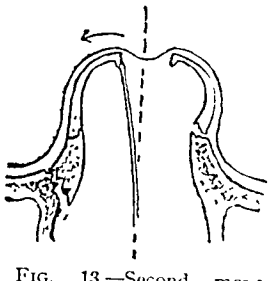

FIG. 13.—Second movement of disimpaction.

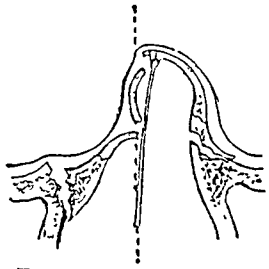

FIG. 14.—Crushing of right side of nose, as in Case III.

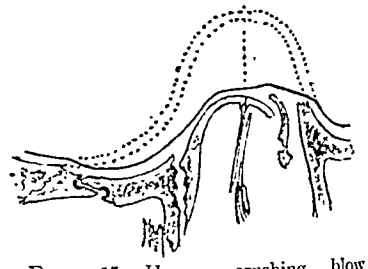

FIG. 15.—Heavy crushing blow involving antrum, as in Cases IV and V.

(Fig. 15). Further, the nasal septum is broken or bent, and occlusion of one or both passages common. Such accidents often lead to serious late deformity, calling for special reparative operative procedures; as, for example, by cartilage grafting, one method of which was described in my article in the *British Medical Journal* of November 28th, 1925.

The need for such measures can be largely avoided by timely reposition; a photograph showing the normal profile, if available, is of considerable value. In dealing with the external deformity one is not troubled by impaction. The fragments are only too mobile; with the forceps they are readily restored to the normal position, but can seldom be retained without support. For this purpose the ordinary nasal splints leave much to be desired; they are difficult to fit, more difficult to fix, and if large enough to be effective still more difficult to withdraw.

To meet this situation I have devised a wire splint which supports the bridge of the nose by counter-pressure on the nasal floor. It is prepared as follows. With narrow rubber tubing, such as that used in the Carrel technique, cover about 16 inches of malleable silver wire of 1/20 inch diameter (= 18 s.w.g.) Bend P: bend the wire in the centre so that it forms a long narrow U, the legs about 1/4 inch apart. Bend Q: holding the U the portion below S is brought up beneath the depressed part of the nose, and the angle Q R S is opened (Figs. 19 and 20). Make sure that the splint really does support the front of the nose when the forceps are withdrawn, that it is securely fixed, and that the nose is symmetrical. Tie the splint below T to the portion between P and Q which rests on the philtrum. Turn the free end outward round the base of the ala nasi to prevent upward displacement (Fig. 21), and cut off any portion that is redundant.

A piece of strapping may be used across the upper lip and projecting part of the splint if additional security is desired. But the splint is genuinely self-retaining, is well tolerated for eight to ten days, does not get foul, and permits of nasal lavage and at least fair nasal respiration. When removal is desired the steps just described are reversed. In these cases, provided antero-posterior reposition is good, there is seldom much difficulty in securing bilateral symmetry; the profile affords the best criterion of success or failure.

CASE II

This patient was attacked by a man armed with a knuckle-duster or a metal bar, and the bridge of his nose was beaten flat. The triangle splint was used for seven days, with the satisfactory result shown (Fig. 5 on Plate).

Case III

A girl was involved in a collision between her cycle and a motor lorry. The deformity resembled the simple type, but radiographic examination showed that the right nasal bone had been crushed in against the septum, and the frontal process of the maxilla fractured off, though the left side of the nose was comparatively little affected (Fig. 1 on Plate; compare Fig. 14). The triangle splint was employed for seven days and a perfect restoration achieved.

The nasal septum can sometimes be reduced into place by forceps pressure and manipulation. Should this fail, it is best at once to resect the damaged portion by the submucous route; for the profile of the nose beneath the nasal bones (except that of the tip) is supported by the anterior edge of the quadrilateral cartilage; and while that is distorted, restoration of symmetry may prove impossible.

Another complication of severe crushing is fracture of the body of the maxilla, the line of cleavage often running from the orbital margin at the maxillary-malar suture downward, inward, and backward (Fig. 15). The large fragment thus detached may become impacted in the antrum which the fracture has opened, producing by distortion of the orbital margin a most peculiar appearance. It may be possible to lever the fragment up into place by passing a blunt instrument up the nostril, taking care that this does not slip upward toward the roof of the nose. If that fails, convenient access may be obtained by an incision in the mucous membrane of the canine fossa, reflecting the periosteum as if for a Scanes-Spicer antrostomy. Where an angle or spike of bone prevents restoration it may have to be clipped off with bone-cutting forceps.

Case IV (Fig. 2 on Plate)

Miss L. was involved in a serious motor accident. I saw her ten days later and found the whole nose had been pushed over to the left, only the tip remaining in the mid-line. The left nostril was completely blocked by the crumpled septal cartilage. The right side of the nose and the adjacent part of the cheek were markedly depressed, with a manifest gap in the orbital margin, the cheek and upper lip were anaesthetic. The skiagram shows the extensive damage to the maxilla, and the opacity produced by blood in the right antrum. Under general anaesthesia the large fragment was levered up into place, where it remained while the second large fragment was elevated; the nasal bones were replaced, and the whole nose now remained firmly set without support; the septal cartilage was resected. The cosmetic result was perfect.

Case V

This lady fell from a ladder, and her nose, coming in contact with the edge of a dresser, was crushed level with the cheeks. A skiagram showed that in addition to comminution of the nasal bones and fracture of the vertical plate of the ethmoid a large piece of the maxilla had been driven into the antrum. In order to reduce the latter it was necessary to approach it via the canine fossa route, to cut off an angle that defied all efforts at reduction, and then to lever it up with a hook passed through the oral incision and an elevator introduced up the nostril. The nose was then restored, and the triangle splint used for ten days. A perfectly straight profile was obtained, the symmetry being well shown in the photograph. (Fig. 6 on Plate.)

Finally, in the most serious cases there may be extensive damage to skin and mucous membrane, or the nose may be almost torn off. Where considerable loss of substance occurs one may have later to undertake elaborate reparative operations—for example, the now well-known tube-graft rhinoplasty that we owe to Sir Harold Gillies. In order to minimize the task of cosmetic restoration we must in the early treatment be guided by two principles. First, preserve every scrap of viable tissue, especially skin and mucous membrane. Secondly, close all wounds, even stitching skin to mucous membrane when necessary for this end, so that healing by granulation with its attendant cicatricial contraction is reduced to the unavoidable minimum. Within the nose we must prevent adhesions between the sides and the septum. A fairly stiff non-absorbent splint is needed, thin enough to be retained without discomfort for days. It can be improvised from a sheet of celluloid, obtained by soaking off the coating of an *x*-ray film in hot water; the thicker celluloid sold for repair of car windows is even better. A very useful splint can be made by folding a piece of strapping "sticky sides in" and dipping in melted hard paraffin wax—for example, ambrine or a good quality candle. It is worth some trouble in the initial stages to avoid extensive intranasal adhesions. At the earliest possible moment such cases should be brought under the care of a surgeon with experience of rhinoplastic technique.

Case VI

This boy was thrown from his motor cycle and brought in unconscious. His nose was crushed, and split in the mid-line, so that the wound gave a good view of the interior. Local

THE SELF-RETAINING TRIANGLE NASAL SPLINT

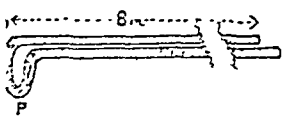

FIG. 16.—Beads P and Q.

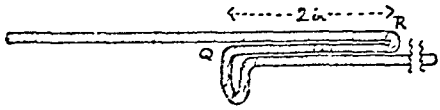

FIG. 17.—Bend R, right side only.

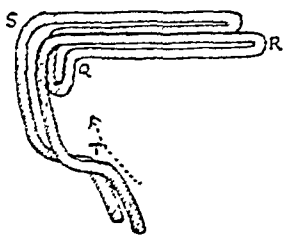

FIG. 18.—The splint ready for insertion.

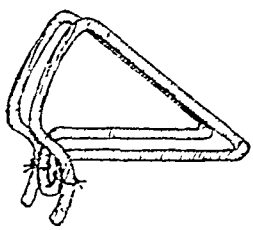

FIG. 19.—The splint expanded and tied.

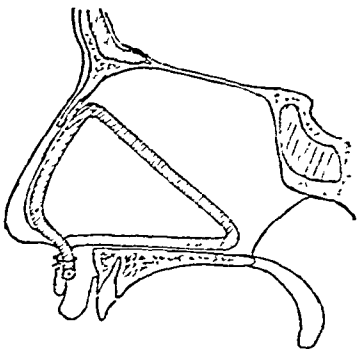

FIG. 20.—Section through left nasal chamber, showing position of splint.

FIG. 21.—The upper lip with splint in position.

measures were directed to careful suture of skin and mucous membrane, and prevention of adhesions. One week later he presented the appearance shown (Fig. 7 on Plate); even in this case the tip of the nose remains central. The fragments of the nasal bones, maxillae, and ethmoid were carefully manipulated into place under general anaesthesia and retained on the triangle splint. The nasal airway is perfect, and the cosmetic result impaired only by the scar (Fig. 8 on Plate).

Summary

The common type of "broken nose" is due to lateral (but not backward) displacement of both nasal bones with imbrication. Treatment consists of (*a*) disimpaction, (*b*) free mobilization of both bones, and (*c*) symmetrical moulding together. No splints are needed.

When the nose has been crushed, internal splinting is required to restore the profile, a convenient form of splint is described. Resection of the septum may be needed. Where a portion of the maxilla is impacted in the antrum access is obtained by the canine fossa route. If much damage has been caused to skin and soft parts, every effort must be made to conserve tissue, limit sepsis, and prevent adhesions.

I am indebted to Dr. F. J. A. Mayes for the skiagrams and photographs.

THE ROLE OF THE PITUITARY IN THE ETIOLOGY OF CANCER

[Preliminary Paper]

BY

WILLIAM SUSMAN, B.A., M.D., C.M.

Lecturer in Pathology, Manchester University; Honorary Pathologist, Victoria Memorial Jewish Hospital.

(*With Special Plate*)

Although many of the functions of the ductless glands remain obscure, it is known that the anterior pituitary concerns itself with promoting growth. However, the prevailing conception of this function of the anterior pituitary is limited to the organism as a whole and not to cell growth, or tissue growth, as seen in repair and disease. Zondek (1930) has shown that in 15 per cent. of 118 cases of malignant disease the anterior pituitary hormone was present in the urine in sufficient quantity to give a positive Zondek-Aschheim reaction in mice. In other words, in neoplastic disease anterior pituitary activity is increased to an appreciable degree in a significant proportion of cases.

That this activity of the anterior pituitary does not in itself cause cancer is evident from the fact that in 98 per cent. of healthy pregnant females the Zondek-Aschheim reaction is positive. The relationship of malignant disease with pregnancy, in that both types of cases may give a positive Zondek-Aschheim reaction, is interesting in two ways. In both there is a tumour present, but the obvious point of difference between the two is that in pregnancy the growth is controlled—a condition lacking in the malignant growth.

Growth-promoting Hormone in Posterior Lobe

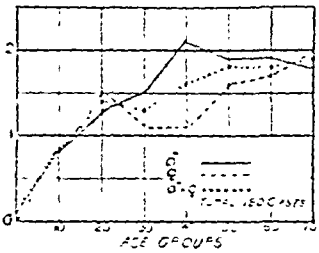
What is responsible for this controlling of growth, whether in the case of a foetus an organ, a tissue, or a cell? A hypothesis suggested itself in the examination of the pituitary from a male, aged 18, showing all the features of renal infantilism, in whom the posterior pituitary was from two to three times as large as the anterior lobe, whereas, in the normal, the posterior lobe is about one-third the size of the anterior. With a posterior lobe about six times as large as the normal, one can expect some positive feature in the body indicative of this exaggerated function of the part, and in the case referred to the exaggerated feature was in all probability infantilism. This suspicion is, to some degree, confirmed by Sharpey-Schafer, who states that if posterior pituitary is grafted into young tadpoles they subsequently show definite retardation of growth. Can it be that the function of the posterior pituitary is to check growth? This would be in accordance with the older view that the ductless glands (considering the pituitary and the adrenal each as two glands) work in pairs, one giving rise to a stimulating impulse, and the other checking the former by acting in the opposite manner.

Although the pituitary is the seat of the growth promoting hormone, and, according to the above hypothesis, of the growth-checking hormone, metabolism is almost as important in the growth process. Hence, in malignant disease, the glands concerned in metabolism must also be considered. That the endocrines might be disturbed in cancer seemed probable. Could the course of the disease be influenced by adjusting the working of any or all of the glands?

Histological Observations

In order to appreciate fully the character of this investigation it would be as well to state now that the ideas expressed in this work gradually evolved during a histological survey of the whole endocrine system—on the pituitaries, thyroids, and adrenals, of over 200 cases, and on the parathyroids, thymuses and pancreases, of increases, of about 100 cases or over. The selection of the material depended entirely on the state of preservation of the tissue, and not on the type of the case. Hence the number of glands from cancer cases was limited.

The following data on the pituitary were from cases examination of 230 glands, of which 30 were based on an of malignant disease—including 13 of glioma cerebri.



Working on Stewart's hypothesis (1931) that the cells of the anterior lobe are merely in different stages of function, and that the acidophilic cells contain the active secretion, I found that the anterior pituitary in the tumour cases did show a degree of activity appreciably higher than in the normal. Histologically Zondek's conclusion that 15 per cent. of cases of malignant disease give a positive Zondek-Aschheim reaction was confirmed. In many, or perhaps all, cases of malignant disease, then, the anterior pituitary might be considered as overactive.

The Posterior Lobe

The posterior lobe of the hypophysis offered a more difficult task. The belief that the posterior part of the gland was essentially neuroglial was found to be untenable. Preparations stained for neuroglia showed the neuroglia distributed as strands about circular or elliptical masses of tissue, and in well-preserved sections stained by haemalum and eosin the parenchymatous character of the lobules was evident (Fig. 1 on Plate). The posterior pituitary, then, consists of lobules of roundish epithelial cells; these lobules were well vascularized and surrounded by a neuroglial stroma. The colloid of this section of the pituitary was taken to be its effective secretion, and appeared to emanate from the epithelial lobules, from whence it passed through the veins of the posterior pituitary, to the vessels of the pars intermedia, where the secretions of both anterior and posterior lobes intermix. If, as already suggested, the secretion of the posterior pituitary is concerned with checking growth, then the lobe of the gland should show changes, with an incidence parallel with that of cancer, in the various age groups, while in cancer cases it should show these and corresponding changes in a greater degree and more frequently.

In this study the brown pigment of the posterior pituitary was frequently found associated with, or in

nasses of colloid. Often, too, the associated colloid was of a greyish colour when stained with haemalum and eosin. The pigment tended to migrate to the perivascular hannels. In general, the impression was that the brown igment represented an altered and perhaps ineffective ecretion. For purposes of comparison the pigment in ach gland was gauged to be scanty, of moderate amount, r abundant, and in order to produce a graph these grades ere evaluated as 1, 2, and 3. The arithmetical average or 180 cases is shown in the graph (reproduced below),

lotted against the age groups. The results are of necessity very crude, but the curve is sufficiently characteristic to indicate that this pigment increases quite rapidly up to the age of fifty years, and probably slowly from then onwards. This corresponds with the frequency of cancer. The graph shows that brown pigment in the posterior itary tends to increase with age.

he numbers in each age group are:

Age group	Male	Female	Total
0–9	9	3	12
10–19	10	8	18
20–29	16	8	24
30–39	15	8	23
40–49	23	16	39
50–59	27	9	36
60–69	8	11	19
70 and over	6	3	9

the thirty glands from tumour cases there were nine showed a considerable amount of pigment in the ior pituitary; twenty-one showed enough sclerosis recognizable under the low power of the micro-; nine had both sclerosis and pigment present; and o cases the posterior section was considerably com-ed by a large cyst originating in the pars intermedia; x cases, however, no obvious change could be made

Pituitary Changes in Cancer

e histological examination of the pituitary in cancer s suggested: (1) that the anterior pituitary was over-ctive and was stimulating growth; and (2) that the lesions n the posterior pituitary probably affected the quality nd quantity of the posterior secretion, and by so doing, n cancer cases, the growth-restraining influence was nadequate.

As already indicated the growth mechanism was closely ssociated with metabolism. The thyroid and parathyroid glands in cancer cases showed no change which could be lefinitely associated with the disease in question. How-ever, in the pancreas, an important and very significant bnormality was noted.

Changes in the Pancreas

The pancreas was examined in 170 cases, including fourteen cases of cancer apart from carcinoma of the pancreas. The islets in six cases were very numerous, n six numerous, and only in two cases of normal incidence. In all except two cases the islets were enlarged, if the normal islet is taken to be 80 by 110μ (Fig. 2). The groups of cases were certainly small, but these results can be considered to indicate that in cancer cases there is an increased demand for carbohydrate.

Warburg (1923 and 1924) found that, with the same amount of oxygen, cancerous tissue would utilize more carbohydrate, and produce three to four times as much lactic acid as normal tissue. Handel and Tadenuma (1924) showed experimentally that transplanted rat tumours grew more rapidly when the recipient animals were fed on glucose and injected with insulin. Borrel (1922) states that injections of glycogen had an accelerating effect on experimentally produced tumours. Thus the experimental work of others confirms the view obtained from the histological examination of the pancreas in cancer cases. It might be argued that cancer, in these circumstances, should be common in diabetes mellitus. In this disease, however, although the blood sugar is high, there need not necessarily coexist an overactive anterior and a deficient posterior pituitary.

To summarize briefly: in cancer cases there probably exists an unbalanced state in several of the ductless glands which permits the development of the new growth; the following points appear to play an important part—(1) overactivity of the anterior pituitary; (2) underactivity of the posterior pituitary; and (3) an increased demand for carbohydrate, giving rise to abundant and enlarged islets of Langerhans.

Experimental Observations

The experimental phase of this investigation can be divided into two parts: (*a*) to determine whether tumour growth is influenced in the presence of abundant carbohydrate, and (*b*) to determine whether injections of pituitrin would have any effect on checking the growth of epitheliomata in mice.

Effect of Excessive Carbohydrate

One hundred mice were divided into three groups—I of 30, II of 30, and III of 40. All the animals were painted with shale oil five times a week. Group I was fed on oats and cheese; Group II on oats, bread soaked in simple syrup, and simple syrup in the drinking tube. Group III was fed similarly to Group II, but the animals received, in addition, injections of 0.1 c.cm. of a 10 per cent. sterile solution of glucose. These injections varied from three times in the first week to once a fortnight during the first two months. When tumours began to appear, they again received similar injections once a week. At sixteen weeks 30 per cent. of group I, 40 per cent. of Group II, and 56 per cent. of Group III had developed warts. By the twentieth week the first group had 59 per cent., the second group 66 per cent., and the third group 100 per cent. showing tumours. In all, at the thirty-eighth week eighteen epitheliomata had been produced, and of these two occurred in Group I, eight in Group II, and eight in Group III. The incidence of warts in the various groups is not very significant, because the number of animals was too small; but, in view of the results of other workers, these data can be considered as suggestive. The incidence of epitheliomata is much more significant, and appears to show quite definitely that the presence of an abundant supply of glucose does promote the development of epitheliomata in mice.

Effect of Pituitrin

As the epitheliomatous mice became available they were segregated, and the oil applications ceased. In all, thirteen of the eighteen epitheliomata were clinically evident, while the remaining five were recognized only after microscopical examination. Of the group of thirteen, five were used as controls, while the remaining eight were treated. The five controls had the tumours of lesser severity, while the eight animals that were to receive treatment all had severe, extensive, and very obvious epitheliomata. The purpose of the controls was to find

out if any natural regression occurred in the tumours on a basis similar to that which took place in the treated animals. In only one of the control animals did the tumour drop off, and that occurred in a pregnant mouse; but with the termination of pregnancy the growth returned very rapidly.

In the group for treatment, 0.1 to 0.3 c.cm. of a solution of pituitrin (P., D. and Co.) (diluted to 0.1 c.cm. in 35 c.cm. of sterile normal saline) was injected twice daily. The injections were made subcutaneously over the abdomen, or at some point distant to the tumour. The general reactions noted were as follows. Within three days the growth contracted noticeably and became covered with a scab. Gradually the growth became sharply demarcated from the skin. In ten to fourteen days the base became prominent and fluctuant, and from fourteen days onwards necrotic material could be expressed from this region. From a month to six weeks or so, the growth separated, leaving a simple ulcer (Fig. 3), in some cases a few malignant fragments, and in others a thin epitheliomatous layer at the base. Most of the animals died through the wound having become infected, or because of the presence in the body of large numbers of encysted parasites.

Experimental Conclusions

The ultimate results were: (1) complete disappearance of the epithelioma—two cases, four weeks and eight weeks; (2) one or several minute epitheliomatous nodules found on histological examination—four cases, three weeks, five weeks, six weeks, and six weeks; (3) growth reduced to a thin layer at base—two cases, four weeks and nine weeks. It was thus shown, experimentally, that, in mice, the presence of glucose in abundance has a stimulating effect in producing epitheliomata, and that, within limits, pituitrin has a checking influence on malignant tumours. The experimental field was obviously limited; the results obtained, however, were in accordance with the theory enunciated on the basis of the histological findings. Consequently the application of the theory in the therapy of human cases was justifiable. The investigation in its subsequent stage was therefore of a clinical nature.

Remarks on the First Group

Up to the present stage no means were available by which the anterior pituitary could be controlled, and hence the only therapeutic means available were: (1) a diet low in carbohydrate to starve the tumour, and (2) pituitrin (P., D. and Co.) to check the malignant growth. The cases in this group were four in number, and when treatment commenced the average expectation of life was only a few weeks at most, for the growths were all very advanced.

Case I

Male, aged 49. Primary carcinoma of tongue with bilateral involvement of submaxillary gland and extensive infiltration into the neck on both sides. There was a large tumour-like swelling on both sides of the chin, and in each tumour there was a small sinus. General condition was fair and cachexia moderate.

Treatment.—Low carbohydrate diet; 0.5 c.cm. to 2 c.cm. of pituitrin (P., D. and Co.) twice daily. At the end of three weeks the patient died. After the first week the discharge from both sinuses progressively increased, and the sinuses enlarged. After the second week, the submaxillary tumours had visibly diminished in size. At necropsy no growth was found in the tongue, while the submaxillary growths were soft, crumbly, and necrotic; but firm tumour tissue was present in the peripheral shell (Fig. 4). A mediastinal secondary was in a similar state. The cause of death was fatty infiltration of the heart and cirrhosis of the liver.

Case II

Female, aged 59. Epithelioma of right cheek about 12 cm. in diameter, of the cauliflower type, and with an extension down the lateral side of the neck. General condition bad. Cachexia advanced. Treatment similar. After five and a half weeks of treatment, this patient died in a highly toxic state. At necropsy the cauliflower growth had been reduced to a nodule 2 cm. in diameter, but the original base was still malignant. The mass on the side of the neck was hollow and contained clear fluid. Extending below and behind the right eye there was a mass of necrotic tumour tissue. Cause of death—fatty degeneration of the myocardium.

Case III

Female, aged 61. Recurrence of carcinoma of the left breast in surgical scar and in adjacent area, after radical amputation. The area involved was 12 cm. by 18 cm. over the lateral and anterior aspect of the left breast. Condition poor, cachexia moderate. Treatment similar for the first six and a half weeks. At six weeks the malignant edge had begun to disappear, and the centre of the wound seemed to be clearing of growth. The involved area became irregular through some healing having occurred from the sides.

Case IV

Female, aged 44. Carcinoma of both breasts. Both breasts were very prominent, and growth had ulcerated through the right breast in the region of the nipple. Condition poor. Cachexia advanced. Malignant growth advanced. Treatment similar for the first six and a half weeks. During the first week the area about both breasts became intensely congested and denuded of skin. The necrosis in the right breast progressively increased, and at three weeks both breasts appeared to have decreased in size; at one month after treatment the left breast was no longer fixed.

Commentary

In all the four cases in this group there was intense pain in the tumour three to ten minutes after each injection, which lasted for about half an hour. This began at the growing margin and spread over the whole tumour. In all cases, too, the diastolic pressure increased, leaving the pulse pressure at twenty minutes after an injection as low as from 16 to 20. This, however, was transient. More troublesome was the small amount of urine which was periodically recorded, but the amount returned to normal when the dose of pituitrin was reduced, or, if necessary, omitted for that day. Signs of an overdose of pituitrin occurred occasionally, and in the form of spasm of the occipital, brachial, or femoral arteries. One case showed dilatation of the pupils, and at another time the systolic pressure rose by 100 points. Fortunately, these were all transient.

During the six and a half weeks included in this period, when the treatment consisted only of injections of pituitrin and of a diet low in carbohydrate, all the growths showed definite regression. In all cases, however, this regression appeared to come to a standstill, and for a time it seemed that this line of approach to the treatment of malignant disease would be of a very limited character. It was at this point that the Zondek-Aschheim reaction in its relationship to malignant disease was considered, and by this means a method for restraining the activity of the anterior pituitary presented itself.

Remarks on the Second Group

Zondek showed that in 15 per cent. of 118 cases of malignant disease the Zondek-Aschheim reaction was positive. The unpublished results of eighteen cases investigated by Susman and Nuttall showed that fourteen gave a positive reaction; these included four of the six cases in both groups. The remaining two have not been tested. In short, it has been a working rule to suppose

that every case of cancer has a hyperactive anterior pituitary, for it was found that several of the fourteen cases which had previously given a negative reaction became positive if the test was repeated several times. Case II presented a further interesting point. The patient was obviously in a highly toxic state. Her urine, when injected into mice, was lethal. When the urine was diluted twenty times the Zondek-Aschheim reaction was very definitely positive. In other words, the reacting hormone was present in very great amount in the undiluted urine, and it was just possible that it was the excess of anterior pituitary secretion which caused the profound toxæmia. Zondek (1930) found that in cases in which castration had been performed by operation 75 per cent. gave a positive reaction, and this included bilateral oophorectomy. This suggested that the genital glands had a restraining influence on the anterior pituitary, and that perhaps, by the administration of an ovarian extract (theelin, P., D. and Co.), the overactivity of the anterior pituitary in malignant disease might be controlled. The therapeutic agents utilized in Group II were then (*a*) a diet low in carbohydrate, to starve the growth, (*b*) pituitrin (P., D. and Co.), to reinforce the secretion of the posterior pituitary, and (*c*) theelin (P., D. and Co.), to restrain the overactivity of the anterior pituitary.

Case III

Treatment continued as in Group I with the addition of 0·25 c.cm. of theelin daily *for three weeks* and then once or twice weekly. The malignant area continued to clear. In two months the central area was largely cleared but there probably remained a thin base of malignant tissue. In three months the malignant edge was no longer apparent and the surface was flat and clean. The appearance was good but the area was probably not entirely free from growth.

Case IV

Treatment as in Group I with the addition of 0·25 c.cm. to 0·5 c.cm. theelin once daily. Necrosis of the right breast continued and by the tenth week the right breast was reduced to a layer of tumour tissue on the chest wall. The left had become much reduced in size. *Progress continues.*

Case V

Male, aged 55. Epithelioma of tongue with involvement of floor of the mouth and left submaxillary gland. Tongue was fixed and patient was unable to speak.

Treatment.—Diet low in carbohydrate, pituitrin 1 c.cm. to 2 c.cm. twice daily and theelin 0·25 c.cm. to 0·5 c.cm. daily. Within two days his speech was understandable. At the end of one month the tongue was cleaner, not so large, and slightly mobile. Pain in the tongue was severe after injections. The patient looked well and felt well.

Case VI

Female, aged 76. Slow growing epithelioma (Fig. 5) on the dorsum of the foot, 2·6 cm. by 3 cm., with an actively infiltrating edge on the right side and hyperkeratosis on the left (Fig. 7).

Treatment.—Diet low in carbohydrate. Pituitrin from 0·5 c.cm. to 2 c.cm. twice daily and theelin from 0·25 c.cm. to 0·5 c.cm. daily, with occasional lapses for several days. For the first two weeks theelin was not available.

In five days the advancing edge disappeared. At two weeks the tumour was sharply demarcated from the skin and the crescent of tumour tissue at the upper pole was necrotic (Fig. 8). Sections at this stage showed that the tumour was well differentiated from the epidermis (Fig. 6) and was being surrounded by cellular connective tissue. The tumour became very congested and much necrotic material came away in the dressings. At the end of one month the tumour edge was separating, the skin was growing in underneath, and the crescent at the upper pole had disappeared. Since treatment began the tumour was no longer painful. At six weeks a probe could be passed in under the growth over a considerable part of its circumference. At the end of seven weeks the tumour was removed completely and easily by enucleation with a very blunt instrument. When the tumour was removed there could be seen a central area where the tumour had been attached, about 2 cm. in diameter, and an outer rim of skin about 0·4 cm. in width signifying that separation had occurred to the extent of about 0·8 cm. of the diameter of the growth before the operation. Since the operation the patient has been receiving 0·5 c.cm. to 1 c.cm. of pituitrin daily with occasional injections of 0·25 c.cm. theelin. Three weeks after the tumour had been enucleated the wound had healed completely and the patient was discharged from hospital. For the last month the patient has been well and felt much younger.

Case VII

Female, aged 54. Carcinoma right bronchus. Before treatment she complained of a constricting feeling about the trachea and had pleural effusion which caused dyspnœa.

Treatment.—Diet low in carbohydrate. 0·5 c.cm. to 1 c.cm. pituitrin twice daily and 0·25 c.cm. to 0·5 c.cm. theelin daily. In fourteen days the constricting feeling about the trachea disappeared. She looked and felt quite well but respirations continued between 35 and 40. This would be largely due to the intense congestion induced in the affected lung by the treatment. Pain occurred in the right chest after each injection.

Discussion

The crucial test for this form of treatment was in Case VI. There we find that the growing edge disappeared in five days, that the tumour began to separate at fourteen days (at which time the associated hyperkeratosis had disappeared), that in six weeks a probe could be inserted some distance under the growth at most points along the circumference of the tumour and that at seven weeks the tumour, an epithelioma proved by microscopical examination, was successfully enucleated without any cutting. This case alone showed that the treatment based on a definite hypothesis was successful. There is nothing, however, to indicate that recurrences may not happen at some time or other. It is hoped that the patient will continue receiving periodic injections of pituitrin and theelin for at present there is no way of establishing the fact that the normal endocrine balance has been restored.

As for the other cases, all the tumours appear to show some regression, life has been prolonged, and all the patients look and feel better than before. After theelin was employed there has been no serious set back in the progress of the cases and no deaths.

That pituitrin can affect tumour growth was shown by Norgate (1921) when he treated thirty-six cases with injections up to 3 c.cm. a week, but these injections were made into the tumour. He found that it caused an improvement in appetite, in weight, and regression of the tumour. Secondaries were rare. On the whole, life was prolonged for a year or more. He concluded that pituitrin only delayed growth by cutting off the blood supply. Carne (1918) injected pituitrin in cancer cases to raise the blood pressure, and he found a noticeable improvement in the cases so treated. Neither of these inquiries was based on a belief that the ductless glands might play an important part in cancer.

The pain which followed after the injection of pituitrin in cancer cases was investigated by Reding and Slye (1926), who found that this phenomenon occurred in 80 per cent. of eighty cases. No pain was complained of by patients suffering from a non-malignant ulcer, tuberculous or syphilis. They concluded that the pain was not due to vaso-constriction and that the phenomenon was neither restricted to any particular type of growth nor dependent on the amount of smooth muscle in the part.

In conclusion, only a few more points need be dealt with. Pain was controlled by morphine or its equivalent. When the output of urine came below 20 ounces the dose of pituitrin was reduced and if necessary stopped. The output of urine invariably returned to normal in a day or

two. The low pulse pressure which frequently occurred after an injection of pituitrin merely caused a transient faintness. Finally, the effectiveness of the dose was gauged by the temperature, for when the temperature varied between 97° and 99° it was judged that the regressive changes were sufficient. When toxic absorption caused the temperature to rise above 99°, the usual measures were employed to bring it down.

Summary

1. Based on the hypothesis that in cancer cases the anterior pituitary was overactive, and the posterior pituitary underactive, two cases of advanced cancer were treated with pituitrin alone, and five cases with pituitrin and theelin. All were placed on a diet low in carbohydrate.

2. An epithelioma began to separate off and was enucleated after seven weeks of this treatment. The growing edge disappeared in five days.

3. All the cases showed regressive changes in the tumours, and life appeared to be definitely prolonged.

I wish to thank the honorary, medical, and nursing staff of the Christie Cancer Hospital, and Dr. Stanley White of Messrs. Parke, Davis and Co., for their valuable co-operation in the clinical work. I am indebted to the Manchester Committee on Cancer, and the Manchester University Grants Committee for grants to defray the expenses of this investigation. For the photographs and photomicrographs I have to thank Mr. H. C. Taylor of the pathological department.

TORSION OF OVARIAN CYST IN CHILDREN

BY

W. ARKLAY STEEL, M.D.St. And., M.R.C.P.Lond.

REDHILL HOSPITAL, EDGWARE

(*With Special Plate*)

The age incidence of ovarian tumours has been noted in several valuable series of recorded cases. Statistics indicate the occurrence of ovarian tumours at the extremes of age and their comparative infrequency in childhood. The proportion of cases met with in children does not exceed 3 per cent. Illustrative of the early age at which ovarian tumours may appear is the case reported by Doran of an ovarian tumour in a premature child, aged 7 months. Another instance is given by Chiene, who performed ovariotomy on a child aged 3 months. The majority, however, of these tumours in children are met with between the ages of 10 and 14. Both the solid and the cystic types of tumour of the ovary are found in children. Of the simple variety, cystadenomata and dermoid cysts are equally common, and constitute about two-thirds of all tumours. The malignant growths form the remainder, and, of these, sarcomata are rather more common than carcinomata.

Cases of ovarian tumours are brought to our notice by reason of: (1) their increasing growth giving rise to abdominal deformity; (2) constitutional disturbances; (3) mechanical effects, causing pressure on the surrounding viscera; (4) complications. In children the complications of rupture, or of suppuration of an ovarian cyst, are exceedingly rare, and torsion, although the commonest complication, is relatively uncommon. The rarity of the condition justifies the detailed description of the following case, which was under my care.

Illustrative Case

J. L. M. J., female, aged 9 years, was admitted to hospital on October 13th, 1930, as a surgical emergency. The parents were both healthy, but somewhat dull intellectually. There was one other sister alive and well.

Previous History.—The patient was born after a short and normal labour, and, except for measles and whooping-cough, she had always been very healthy. When about 5 years of age she had an attack of pain, which commenced on the left side and extended across the upper part of the abdomen. This was accompanied by retching, and "trouble with the bowels." These attacks recurred each year, but were never severe enough to confine the child to bed. The mother was emphatic that the onset of each attack synchronized with the approach of the colder weather, taking place usually in October. The pain lasted as a rule for fourteen days, but eventually responded to doses of castor oil. She had had attacks of vague abdominal pain frequently throughout the last year.

Present Illness.—At 9 p.m., on October 5th, 1930, the patient had a sudden attack of vomiting. There was no pain at first, but the next day she complained of pain in the left side of the abdomen. This pain extended across the upper part of the abdomen, and in no way differed from that experienced in previous attacks. She attended school from October 7th to 10th, but at 11 a.m. on the latter date she had a sudden attack of pain, which "doubled her up." The pain started in the left side, and passed down to the left groin and across the abdomen. She vomited several times. None of the measures which had been successful in previous attacks relieved the pain. The child had a peculiar taste for castor oil, and of her own accord frequently took copious draughts straight from the bottle. There was no action of the bowels from October 9th until the 13th, when she passed a normal motion. Micturition was normal up to the day of admission, when she complained of burning pain on passing urine. The abdominal pain continued, and her general condition became gradually worse. She was sent to hospital as a case of acute appendicitis.

On later interrogation, the mother said that for the past three years she had noticed her child's abdomen becoming more prominent, and that it "seemed to be getting hard on the left side." The patient often acted in a peculiar manner, and the mother was inclined to regard her as somewhat "simple-minded." She had never menstruated, nor was there any precocious sexual development.

Examination.—On admission the patient was extremely ill and dehydrated, crying out from time to time owing to spasms of pain. The temperature was 100.8° F., pulse rate 124, respirations 24. The tongue was furred and dry. The upper part of the abdomen moved slightly with respiration, the lower part not at all. A globular swelling, extending from the pubis to the umbilicus, was apparent, filling the hypogastrium and extending to the left side. Palpation confirmed the presence of this swelling, which was felt to be tense, tender, and cystic. It appeared to rise from the pelvis, and was rather more prominent on the left side. It was so centrally placed, however, that the possibility of its being bladder was considered. Catheterization was performed, but had no effect in diminishing the size of the tumour. There was generalized tenderness over the abdomen and in the loins. Rigidity was present over the whole abdomen, but was most marked in the muscles overlying the tumour, especially on the left side. On rectal examination a hard, tense, tender, and cystic swelling was felt filling the pelvis, and so bulging the anterior wall of the rectum as practically to occlude the lumen of the bowel. A slight degree of vulvitis was present, with a scanty yellowish discharge. The examination of the urine showed the presence of ketones, but was otherwise normal. The other systems revealed nothing abnormal. The diagnosis of acute appendicitis was excluded. The condition was thought to be an abscess, circumscribed in the pelvis, due possibly to an extension from the vulvitis. An operation was decided upon, and was performed at 11.50 p.m. on October 13th.

Operation.—Under chloroform and ether anæsthesia the abdomen was opened by a right paramedian incision. A large, mottled cyst presented itself in the wound, its upper limit extending above the level of the umbilicus. Further examination showed this to be a left ovarian cyst which completely filled the pelvis. The pedicle was found to have twisted three and a half turns in a clockwise direction. Delicate adhesions were present between the cyst and the posterior aspect of the infantile uterus, and these were readily separated. The right ovary was normal. There was some clear sanguineous fluid in the pelvis. The pedicle was clamped and ligatured, and the cyst removed. The stump was peritonized, and the abdomen closed without drains. The child made a complete recovery, and was discharged on October 29th.

Morbid Anatomy.—A photograph of the specimen (see Special Plate) shows an ovarian cyst with a broad thinned pedicle and also part of the Fallopian tube which was excised with the tumour. The cyst was thin walled, somewhat mottled in appearance, due to the deposition of fatty particles on the inner side. The contents were clear fluid in which were floating globules of fat and also fine hairs. The tumour is a typical dermoid cyst and measures 4½ by 4 by 4 inches.

Features of the Condition

In a somewhat extensive review of the literature dealing with cases of torsion of an ovarian cyst in children, it is noticeable that, although cases have been reported in greater or less detail, very little attempt has been made to correlate the clinical findings of the condition. In several instances, more stress has been laid on its rarity than on the description of the actual case itself and the recognition of its possibility in diagnosis. In the above case and in those reviewed there are many common features which warrant fuller description.

Pain.—In many instances a history is reported of similar attacks, which have been of less severity, but have recurred at intervals of months or, less frequently, of years. These previous attacks are of short duration, lasting in the majority of cases but a few hours, although they may continue for several days. In the acute attack the pain is often preceded by vomiting, or vomiting may occur after the pain and be almost continuous throughout. The onset is sudden, and the pain is very severe in character, being usually constant, but sometimes assuming a spasmodic character. It is definitely localized to the side on which the tumour is situated, but radiates medially across the abdomen, so that the umbilicus may be indicated as the site of the pain. The severity of the initial excruciating pain may diminish after a varying time, leaving a dull ache.

General Condition.—The patient looks ill and may be definitely toxæmic. She is exhausted and apprehensive, often crying out from time to time, owing to spasms of pain. The tongue is furred and dry, and the bowels have usually opened naturally, or have responded to laxatives. In a few cases there may be a history of constipation of several days' duration. The pulse rate is raised, while the respiration rate is normal. The temperature is raised usually above 100°, but it varies between 99° and 103°.

Abdominal Examination.—A tumour can be recognized in the majority of cases; in twenty one cases in which the situation has been given, the cyst has occurred thirteen times on the right side and eight times on the left. The cyst may produce only a general prominence of the abdomen, but in many instances the tumour is definitely demarcated. It may be outlined in the iliac fossa, but frequently it assumes a median position, and gives rise to the false impression that it is a distended bladder. The tumour is tense and fluctuating. Tenderness is present, and is most marked over the site of the tumour. It may be localized to a very small area in the iliac fossa or may be general over the whole abdomen. In one case, no pain or tenderness was experienced. Rigidity occurs and is usually well marked, especially in the muscles overlying the tumour, but it may be generalized.

Rectal Examination.—A rectal examination appears to have been made in relatively few of the cases, but when carried out a definite mass was always palpated in each case. In some instances this appeared to occupy practically the whole of the pelvis and markedly compress the walls of the rectum. The tumour is rarely movable. It is acutely tender, and gives a feeling of fluctuation to the examining finger.

Age Incidence.—The age in this series varied, the oldest patient being 13 years, the youngest was reported by M. L. Harris, who describes a case in which a twisted malignant ovarian tumour was successfully removed from a child aged 22 months.

Complications.—In a few cases a slight degree of vulvitis has been present. A blood stained serous fluid is often found in the abdominal cavity, but it is of too small amount to be appreciated before operation. There may be small areas of localized peritonitis, and recent or established, adhesions are usually present, which can be readily broken down and give rise to no difficulty in the operation. In several cases the appendix, which may be congested, has been found adherent to the cyst. In one case intestinal obstruction due to twisting of the ileum following removal of a cyst rendered a second operation necessary.

Diagnosis

More than twenty five cases of torsion of an ovarian cyst in children have been investigated. Since this investigation a further case has been published and I have heard of the occurrence of yet another. Possibly therefore, it is a commoner condition than the few published cases would lead one to believe. It is thus a striking and humiliating fact that, of all the cases investigated, only four were diagnosed prior to operation—surely an indication that ovarian cyst, quite apart from torsion, had not been considered in the differential diagnosis. Each case has been regarded—and rightly so—as an abdominal emergency requiring operation. The diagnosis most commonly made is that of a localized appendix abscess, and where there is a history of previous attacks, increased temperature and pulse rate, tenderness, rigidity, and vomiting and especially where there is a right sided tumour, it may be extremely difficult to differentiate the two conditions. In a case of torsion of a cyst, the onset as a rule is sudden, the bowels have been regular, and the presence of a tumour can be made out by abdominal and rectal examination from the very commencement of the attack. The diagnosis of intussusception has been suggested, but the clinical features of this condition, its greater frequency during the first year and in boys, the passage of mucus and blood in the stools, and the typical emptiness of the right iliac fossa, are absent in the ovarian lesion. Abscess formation must be excluded, and if no definite causative factor can be established to account for it, an abscess, circumscribed in the pelvis, may give rise to great difficulty in diagnosis. The knowledge that torsion of an ovarian cyst can so closely simulate an acute suppurative lesion should render it possible for a correct diagnosis to be made more easily and more frequently.

Summary

1 Over twenty five cases of torsion of ovarian cyst in children have been reviewed, and an illustrative case is given.

2 Ovarian tumour, though rare, increases in frequency with the age of the child, and is most commonly met with between the ages of 10 and 14.

3 Torsion, although very rare, is the commonest complication of these tumours.

4 A correct diagnosis of the condition is decidedly more often the exception than the rule, in spite of the fact

that a constant clinical picture is found in practically every case.

5. The typical features present are: a history of similar but less severe attacks, the sudden onset of pain, an increase of temperature and pulse rate, the palpable abdominal tumour, with overlying tenderness and rigidity, and the tender cystic mass, which can be made out per rectum.

6. The diagnosis is sometimes very difficult, the lesion for which torsion of a cyst is most often mistaken being an appendix abscess.

I have to thank Dr. Teale, who kindly examined the tumour for me and also furnished me with the photograph. The specimen is now in the Pathological Museum of University College Hospital.

GANGRENE OF THE SKIN OF DIPHTHERITIC ORIGIN

BY

J. S. ANDERSON, M.A., M.D., D.P.H.

MEDICAL SUPERINTENDENT, LEEDS CITY HOSPITALS; LECTURER IN INFECTIOUS DISEASES, UNIVERSITY OF LEEDS

(With Special Plate)

Two types of diphtheritic infection of the skin may be described. In one a diphtheria organism is isolated, but no symptoms characteristic of the disease are present. This type, which is not uncommon, would probably be more correctly regarded as bacteriological diphtheria. In the other type the diphtheria organism is the active agent in the production of the local disease. This type is of rare occurrence. Cutaneous diphtheria is usually found to be secondary to diphtheria in some more normal site, such as the fauces, nose, or genitals, but primary diphtheria of the skin may occur. The absence of a source of origin of the infection, and the unusual site of the disease, combine to make the present case worthy of record.

The patient was a boy, aged 11 years. According to the history, he visited a swimming bath on May 20th, 1931, and sustained a slight injury of the nature of a bruise on the dorsum of the right foot. Persistent pain and discomfort led to his attendance at the Leeds Public Dispensary on May 26th. The house-surgeon described the injury then as showing the usual appearance of inflammation and the semblance of a greyish pellicle in the centre. At first sight it was taken for a burn. The lesion progressed until, by June 1st, there was a surrounding zone of cellulitis, with, in the centre, a triangular area, which was dark grey and later black, and suggested a localized form of gangrene. Incisions into the affected area revealed no pus and produced no improvement. On account of the unusual appearance of the lesion he was retained as an in-patient. Slight general disturbance was noted from June 1st to 3rd, but the temperature did not rise above 99°. On June 4th, however, it rose to 104°, and multiple small incisions were made in the surrounding inflammatory area. At the same time a swab was taken. On June 5th and 6th the temperature hovered around 102°, and no improvement was noted. On June 6th, following the receipt of a report that diphtheria organisms were present, he was transferred to the Leeds City Hospital.

Fig. 1 (Plate) shows the appearance on admission to the Leeds City Hospital. The central area (C) consisted of a dry black eschar. Surrounding it was a greyish pellicle of semi-necrotic skin (B), and the remaining part of the dorsum of the foot showed much inflammation and oedema at (C). Neither lymphangitis nor adenitis was noted. No offensive odour was associated with the lesion. The tonsils were slightly enlarged, but there was no sign of inflammation or of exudate. There was no nasal discharge, and the anterior nares appeared healthy. The temperature was now subnormal and the pulse 90. Albuminuria was present. The Schick test was positive. Diphtheria antitoxin, 16,000 units, was administered on the day of admission, and no treatment other than dry dressings was applied to the foot for the next ten days.

Within twenty-four hours of admission the inflammatory reaction commenced to subside. The greyish pellicle ceased to extend, but became necrotic within the next few days. Eleven days after admission (Plate, Fig. 2) the lesion had taken the form of a crater with well-defined margins, and with a floor of dry, black, necrotic skin. After a further eight days, the necrotic tissue sloughed, leaving a healthy-looking granulating surface. Albuminuria persisted throughout the whole period of isolation, but no other complications were noted. By the end of July the ulcer had healed completely, and he was discharged from hospital on August 12th.

Note on Bacteriology.—The swab taken on June 4th was examined at the Bacteriological Department of the University of Leeds, and the report stated that *Corynebacterium diphtheriae* was present in pure culture. The organism gave the correct sugar reactions, and was proved to be a virulent type. On the day of admission to the Leeds City Hospital swabs taken from the nose and throat showed no diphtheria organisms, while a swab from the inflammatory area showed a pure culture of *C. diphtheriae*. On June 9th swabs from the necrotic skin and from the greyish pellicle also showed *C. diphtheriae*. On June 10th a swab taken from the greyish pellicle was again examined at the University of Leeds, and the report stated that aerobic and anaerobic cultures showed *C. diphtheriae* in pure culture. A nose swab was again negative on June 12th. On July 1st diphtheria organisms were still grown from the floor of the ulcer, but after July 5th swabs were negative.

I am indebted to the Bacteriological Department of the University of Leeds for laboratory work, and to Dr. J. F. Galpine, for helpful information regarding the early stages at the Leeds Public Dispensary.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

A CASE OF WOUND DIPHTHERIA

(With Special Plate)

The false membrane type of diphtheria of a wound and surrounding skin, once seen, cannot readily be forgotten.

A girl, aged 11 years, was admitted to the Royal Victoria and West Hants Hospital on February 2nd, 1929, on account of appendicitis. For four weeks, off and on, she had had abdominal pain of varying intensity in the right iliac region, with obstipation but without nausea and vomiting. When she was admitted the pulse rate was 104, the tongue was furred, and there was local tenderness with rigidity. On February 19th, Mr. Kinsey Morgan removed an inflamed appendix through a grid-iron incision, then closed the wound in the usual way.

On March 4th the wound began to look unhealthy, and was discharging a thin, watery fluid. The temperature had begun to rise. By April 18th the wound was gaping, and was covered by a dirty grey slough, the appearance of which at once suggested a diphtheritic infection. Examination for the Klebs-Loeffler bacillus was ultimately found to be positive, the organism being reported as occurring in almost pure culture. The wound at its worst had opened up so as to measure about 4 inches by 2¼ inches, the external oblique muscle forming the floor; the skin edges were overhanging all round. The exudate was dirty grey in colour, moist, and fibrinous, and spread for some distance on to the skin beyond the wound edges. The exudate beyond the wound was abruptly marginated, the whole being surrounded by an inflamed deep-red areola. No portion of the exudate could be wiped away. The evolution was slow, the whole condition taking about two months to develop. At no time was there any degree of toxaemia; in fact, there was surprisingly little constitutional disturbance. Large doses of antitoxin were given intramuscularly, with eusol and eupad locally, the child ultimately making a satisfactory recovery.

During the war, wound diphtheria was found to be not uncommon. Systemic symptoms referable to the diphtheria toxins did not occur, and the antitoxin appeared to have no obvious effect in ridding the wound of the infection. This false-membrane type (see Plate) is readily enough recognized clinically when one remembers the appearances of the membrane in faucial diphtheria. There are other types of eruption occurring on the skin as the result of infection by the diphtheria bacillus, the diagnosis of which cannot be confirmed without complete bacteriological examination.

I have to offer my thanks to Mr. Kinsey Morgan for permission to publish the case, and to Dr. A. H. Turton for the excellent photograph from which the illustration was taken.

S. Watson Smith, M.D., F.R.C.P.Ed., M.R.C.P.
Bournemouth.

FIBROSED APPENDIX MISTAKEN FOR MALIGNANT DISEASE, CAUSING ILEO-CAECAL INTUSSUSCEPTION

Many mistakes are made in diagnosis; few are recorded. I should like to record one.

Mrs. B., aged 60, called on me at the latter end of December, 1930. She complained of loss of weight, increasing difficulty in emptying the bowels, and a lump in the right side of the abdomen: there was also griping pain. Her knowledge of the lump was quite recent. She said she had been going down-hill for the last eighteen months.

On examination the abdomen was soft, flaccid and undistended, with the exception of one small distended loop of intestine in the right iliac fossa. There was a distinct hard lump felt in connexion with this. After examining the rest of the abdomen and chest, I came back to the iliac fossa, and to my surprise the lump had vanished. What could be felt now was some indefinite thickening in the caecal region. She was sent home to bed, and with the exception of a slight colicky pain on two or three occasions there was no further complaint up to the latter end of February, 1931. A provisional diagnosis was early malignant disease of the caecum.

On February 23rd, 1931, she suddenly started with severe pain and vomiting, the vomit consisting of green and yellow bile. I saw her on the 26th, the third day from the onset. There was absolute constipation, no flatus being passed, and no result from enemas. There was a large irregular mass in the region of the transverse colon, and to the left of the umbilicus. It felt solid and was quite dull on percussion. There was a feeling of emptiness in the caecal region. There was no blood per anum. The diagnosis made was intussusception caused by a malignant growth in the caecum.

I opened the abdomen by a paramedian incision and brought the tumour to the surface. There was some free fluid in the abdomen. The mass proved to be an ileo-caecal intussusception. It was not difficult to unravel, as there was a considerable quantity of soft, yellowish lymph between the intussusceptum and intussuscipiens; this looked like pus, and actually was pus. There was a hard mass at the root of the appendix extending for a short distance into the wall of the surrounding caecum. I was still of opinion I was dealing with a malignant growth. My patient being too ill to stand excision, I short-circuited the ileum into the transverse colon (as a preliminary to a Friedländer's operation), placed the caecum in its bed, and through a stab wound passed a drainage tube down to it. Pus flowed from this for three days, when the tube was removed. Three weeks afterwards the abdomen was opened a second time.

The root of the appendix and surrounding caecum formed a hard, firm, leathery tumour. About six inches of ileum, caecum, appendix, ascending colon, and part of transverse up to the anastomosis were removed. The parts were so free and movable that the operation was easy, and was rendered easier by the preliminary anastomosis. On laying open the bowel afterwards, the mouth of the appendix in the fresh state was wide and funnel-shaped. The canal of the appendix was obliterated except for half an inch near the bowel. The appendix cut like a fibroid of the uterus, or a scirrhous cancer. The pathological report was "a fibroid condition of the appendix."

If I could only have rid myself of the obsession that I was dealing with early malignancy a less severe operation would have been justified. But the age, history, loss of weight, and the appearance and feel of the parts confirmed me so much in my opinion that I felt compelled to do a Friedländer, which I had prepared for by the preliminary anastomosis. If a complete excision had not been done, and only the intussusception unrolled, a degenerating structure would have been left, which might easily have become malignant.

My patient has put on 20 lb. since the operation, and has gained immensely in health.

Leeds. J. Stewart, M.B., M.Ch.

Reports of Societies

BLOOD TRANSFUSION

At the meeting of the Medical Society of London on October 26th, with Mr. Herbert Tilley in the chair, a discussion took place on blood transfusion.

Professor Alexander Fleming said that the beginning of modern blood transfusion, which did not become a common procedure until the war, might be ascribed to Landsteiner in 1900, who discovered the grouping of bloods. Seven years later Jansky did much more elaborate testing, and found that human bloods agglutinated into four groups, and he was followed by Moss, who also had four groups differently denominated. Recently there had been proposed a new nomenclature which had merits, and which he hoped would supersede the others. The relation of the different nomenclatures was shown in the following table:

Land-steiner	Jansky	Moss	Suggested New Nomenclature
C	1	4	O
A	2	2	A
B	3	3	B
—	4	1	A B

Certain troubles were encountered in testing bloods. The first of these was a pseudo-agglutination, not a true agglutination at all, found especially among people who were suffering from pneumonia or similar illness. Another

fallacy was due to auto-agglutination. In a few cases the test might be upset because the blood under conditions of bench or room temperature agglutinated its own corpuscles. Yet another difficulty in grouping arose from the constant discovery of subgroups. He had been told that Landsteiner, who had fifteen people working in his laboratory, could tell the blood of each one of them by agglutination tests. But that did not invalidate the fact that the four groups were real entities. One other point was the relative lack of fixed grouping in the blood of very young infants. He showed that in infants under 1 month, out of forty-nine cases, the proportion having fixed groups was 16 per cent. In giving blood transfusion one was giving several different things: fluid, either plasma or serum, red corpuscles, leucocytes, blood platelets, and perhaps certain immune substances. In shock the indication might be for fluid; in sudden haemorrhage, fluid and corpuscles; in septic conditions, healthy leucocytes; in some haemorrhagic conditions, blood platelets. Whole blood had been largely displaced in transfusion by citrated or defibrinated blood. It was reasonable to assume that whole blood was best, containing as it did all the constituents of blood unaltered and in their proper proportions. But the operation, even with the comparatively simple methods now available, was difficult. Citrated blood gave certain reactions and caused some damage as regards bactericidal power. Defibrinated blood left the leucocytes quite undamaged, and had the merit of being the easiest of all methods to apply. Such transfusion could be done with simple improvised apparatus. Finally, he spoke of immuno-transfusion, in some desperate cases extraordinarily beneficial, and in others, equally desperate, having no effect at all. Two procedures which might be classed as immuno-transfusion were the introduction of nuclein into the donor, and the injection of the donor with some hypertonic salt solution, giving rise to considerable increase in bactericidal power.

Dr. H. Letheby Tidy said that when blood transfusion came to the fore during the war the problem in a case of acute haemorrhage in an otherwise healthy man was simply that of refilling a depleted reservoir. But as blood transfusion was increasingly applied conditions became more difficult, and various reactions were set up. The first beneficial effect of transfusion was restoration of the bulk of the fluid; the second, the actual provision of oxygen; and the third, rest and stimulation to the blood forming tissues. This last was a matter of great importance when dealing with the more medical aspects and the more chronic cases in which blood transfusion was carried out. Any organ on which an excessive call was made was apt to give up the struggle and collapse. In anaemia he thought that anything below 30 per cent. haemoglobin was an indication that blood transfusion should be performed, and at 25 per cent. a point was reached when it was imperative to perform such transfusion. It seemed that the procedure might be used even in less advanced cases. He proceeded to speak of the influence of transfusion on the factors which led to haemorrhage. The first of these factors was the coagulation time. Varying statements were made about the coagulation time in cases of anaemia. One statement was that when anybody collapsed from haemorrhage the blood became more coagulable, so that the haemorrhage was, in fact, brought to an end. On the other hand, the statement was frequently made that, in anaemia, blood was less coagulable than normally, the coagulation time was increased, and the result of a blood transfusion was to diminish this time and to increase the coagulability, so tending to bring to an end any further haemorrhage. As a matter of fact, there was no evidence for either statement. There was no relation between coagulation time and the extent of anaemia, though there were very few observations on the effect of blood transfusion on coagulation time, because, of course, transfusion was only performed in emergency, when it was not an easy matter to make additional observations. The clot in normal blood was distinctly firm. Some diseases showed an abnormal clot, though haemophilia, curiously enough, had a normal clot. The clot of anaemic blood was definitely soft, and must be a very inefficient or delicate seal for a bleeding point. A slight disturbance of that clot would cause recurrence of haemorrhage. After showing the results of a test recently made on an anaemic girl, Dr. Tidy suggested that there was a factor not measured by any of these methods which would definitely tend towards recurrence of haemorrhage, though not towards the development of haemorrhage spontaneously. This was a factor undoubtedly influenced by transfusion. On a good many occasions he had tested bleeding time in persons with high blood pressures, and he had never found any difference in their case before and after venesection. So far as he could see, blood transfusion did not raise the blood pressure above about 120 mm., and approximately it did not raise it by more than 50 mm. (that is, if the original pressure was 70 it would be raised to 120; if it was 100 it would still be raised to 120). Turning to special conditions in which blood transfusion was of use, he said that in haemophilia there was not the slightest doubt as to the benefit of transfusion. Its effect was transient, but it was worth having, because the haemophiliac was not always in a state of haemophilia. In jaundice it had been observed that there was a tendency to oozing. Coagulation time in jaundice was normal, though there were exceptions which had unduly biased the view. On the day of death in a case of jaundice there was some evidence that coagulation time might go up to something quite abnormal. Blood transfusion had no effect on oozing in a jaundiced patient. In primary purpura, the haemorrhagic diathesis, everybody who had used transfusion was agreed that it was unreliable; but the only absolute cure was splenectomy, which was associated with a high mortality, and so one had to fall back on something else, and he felt that blood transfusion was the correct procedure. In leukaemia transfusion had no effect, and in aplastic anaemia the position was the same as in haemorrhagic diathesis.

Mr. Geoffrey L. Keynes gave the following indications for transfusion: (1) haemorrhage and shock—traumatic, pathological; (2) pre- and post-operative conditions—gastric or duodenal ulcer; (3) haemorrhagic diseases—haemophilia, melaena neonatorum, purpura; (4) blood diseases—septicaemia; (5) bactericidal infections—pneumococcal peritonitis. The field of utility was certainly expanding. He had always quarrelled with the distinction between whole blood and citrated, because in citration nothing was taken away, only some alteration was made whereby the clotting complex was inhibited. The amount of citrate used was extremely small. It was necessary to use no more than 1 gram of citrate for 450 c.cm. of blood, and it was difficult to believe that this amount, which was destroyed in the body within ten minutes, really produced any profound effect upon the result of the transfusion. He therefore remained an unrepentant "citrationist." As to technique, Fraenkel's needle appeared to him the best instrument for withdrawing blood from the donor. He had a conical flask containing the citrate solution, the blood being run straight into it through the needle. He agreed with what Dr. Tidy had said about the effect of transfusion upon blood pressure; the blood pressure rose to 120 mm., but not appreciably above that point. He proceeded to speak of the London Blood Transfusion Service, an organization

of voluntary donors. The calls on this service had consistently increased, and it was expected that during 1931 the record number of 2,000 calls would have been made. More than 100 hospitals had called for the service. The effect of transfusion had been good, very good, or excellent in more than 50 per cent. of the cases, and in less than 10 per cent. no improvement had been recorded. The number of conditions for which transfusion was carried out in 1930 was 148. In that year 589 cases were medical, 585 surgical, and 217 gynaecological or obstetrical. There were 193 transfusions for one or other form of anaemia. A few problems still remained. One of these was as to the effect on the donor of frequent bestowals. A certain donor in France had given his blood on 450 occasions, and at present in London there was a man who was anxious to emulate his example, but they hesitated to allow him to do so. Blood grouping was apparently still insufficiently familiar to a great many people, so that they persisted in sending for the universal donor, and large numbers of donors of the other three groups were never used.

Dr. F. PARKES WEBER demonstrated the newly modified apparatus for direct blood transfusion after Bürkle de la Camp. The essential feature was that the blood was withdrawn from the donor into a receiver made of "athrombit," which delayed coagulation, so that the blood could be injected directly into the recipient's vein. This type of apparatus had been used at the German Hospital for about the last twenty blood transfusions. On no occasion had the transfusion (mostly of 300 c.cm.) been followed by any rigor. On one occasion it had been followed by a transient urticarial eruption, but that was in a case of very severe chronic ulcerative colitis, in which urticaria had likewise followed an ordinary transfusion of citrated blood on a previous occasion. Of course there should be no delay during the carrying out of the transfusion.

Mr. JULIAN TAYLOR said that Mr. Keynes had lumped together what could not be properly lumped—shock and haemorrhage. Blood transfusion for haemorrhage was successful in every case; in shock it was very different, and in the war uniform failure resulted. It was very difficult in the case of severe injury or drastic operation to decide how much of the patient's plight was to be attributed to haemorrhage and how much to shock. Experience suggested that the haemorrhage could be treated by blood transfusion and the shock could not. Blood transfusion would help in pre-operative anaemia or in those cases in which loss of blood was inevitable during operation.

Dr J. W. CARR asked whether it was common for rigors to occur from blood transfusion, whether a rigor produced any permanent harmful effect, and whether the full benefit could be expected if rigor had not occurred. Dr BERNARD SCHLESINGER described a case of pneumococcal septicaemia in which benefit resulted from immunotransfusion. Mr C. HOPE CARLTON said that in North America the standard method was whole-blood transfusion, and he had given some six or seven hundred such transfusions there. He came back to this country a strong supporter of the whole blood method, but in three years in London his views had been modified; as many reactions were seen with the whole-blood method as with the citrated method. He mentioned two indications for transfusion: to promote metabolism in infants, and for toxaemia in burns and toxaemia associated with acute intestinal intoxication in infants.

Dr TIDY, in reply, said that he had seen cases where rigors had occurred and yet there was apparent benefit. Good results were seen with and without rigor. Mr. KEYNES said that he had never seen a patient in whom a rigor had had apparently any deleterious effect.

THE COMPILATION OF VITAL STATISTICS

In the Section of Epidemiology and State Medicine of the Royal Society of Medicine, on October 23rd, Professor MAJOR GREENWOOD delivered his second annual address from the chair. His subject, suggested by the recent regretted retirement of Dr. T. H. C. Stevenson, a Jenner Medallist of the society, from his official post at Somerset House, was the General Register Office, and particularly the work of William Farr, Dr. Stevenson's forerunner, and the founder of modern medical statistics.

The General Register Office, said Professor Greenwood, was a wonderful institution, and perhaps its publications between 1850 and 1880 contained more valuable contributions to the knowledge of the theory and practice of vital and medical statistics than were made by all other contemporary official and private investigators throughout the world. Even now Somerset House contrived to tell the world more about the way the English lived and died than the staff of the Statistique Générale de France seemed to be able to discover about their countrymen. Yet not one of the pioneers of statistical theory in the eighteenth century was an Englishman, the greatest of them were Frenchmen and Laplace. What names had we to set beside De Moivre and Laplace? True, we had John Graunt, but it was left to foreigners to realize his importance.

William Farr was the son of a farm labourer in Shropshire, whose education, such as it was, was paid for by a local patron. He became a pupil to a Shrewsbury practitioner and, having sat for the L.S.A. examination started practice in London in 1833. Six very hard years must have followed, during which excursions were made into medical journalism, and then, in 1839, came his appointment as compiler of abstracts in the new General Register Office, a post which he retained until 1880. From the first Farr's hand was seen in the annual reports. The reports of the Registrar General, and, after 1841, of the Census Commissioners, were evidently the compilations of Farr. The letting loose in this way of an inquisitive widely read enthusiast, with a flair for the meaning of statistical statements, was a great piece of luck. How he organized the vital statistics need not be told, for it was part of the common knowledge of educated men. How directly and indirectly—through Simon—he stirred the public conscience was also known. Perhaps his curious little hunts of statistical hares were less appreciated, but a young medical statistician in want of a subject for research should read the annual reports steadily; he would find in their pages a sufficient number of suggestions for innumerable theses.

On his retirement in 1880 Farr was succeeded by William Ogle, the originator of corrected or standardized death rates, and after him came Tatham, also a competent statistician, but the individuality or quaintness which had made the publications of the office so attractive had evaporated. Then began the epoch when Dr. T. H. C. Stevenson occupied Farr's chair and recaptured his spirit. Not that he wrote like Farr, but, like Farr, he had been interested, to use a Farr-like metaphor, in the people going up and down to Camelot, whose shadows appeared in the mirror of Shalott, set up in the Strand. He had told the story of infant mortality in a way to inform the mind and touch the heart. It was now, of course much more difficult to give an official vital statistician his head in the way that George Graham, the second Registrar-General, gave Farr his head. Eighty years ago politicians did not take medical statistics seriously, but now the news value, the tendentious interpretation of medical and vital statistics, could be no longer ignored. It was possible that a department might have to restrict the limits within which the members of its staff had a free hand. It was a choice had to be made between accuracy and [illegible] dullness, there could be no doubt in which direction

official prudence must point. But still the memory of that enthusiast from Shropshire, who was so odd a civil servant and so English a genius, would be honoured, and most of the things he valued would continue to be valued.

A vote of thanks to Professor Greenwood was accorded on the motion of Sir William Hamer, seconded by Sir George Buchanan.

DEAFNESS

At a meeting of the London Jewish Hospital Medical Society on October 8th Mr. Maurice Sorsby delivered the presidential address, on deafness and its prevention. He drew attention to the extreme frequency of deafness in its different degrees; in 1927 there were 4,038 totally deaf children in England and Wales, as against 1,925 children totally blind. Minor auditory defect was present in about a third of the school population, and even more frequent in the adult population. Deafness present at birth, the so-called congenital deafness, was responsible for only a small proportion of deafness seen in adults; the large majority of deaf people acquired their disability. Even congenital deafness was, in most cases, not an hereditary lesion, but a sporadic affection of unknown origin. The presence of a deaf relative, or even of a deaf parent, was no proof that the congenitally deaf person was the subject of hereditary deafness, nor was absence of deafness in the parents evidence that the deafness was not hereditary, for the parents might be carriers of it without themselves being deaf. The truly hereditary deaf offered a serious social problem, owing to their tendency to intermarry. Graham Bell had gone so far as to speak of the formation of a deaf variety of the human race as a result of this inbreeding. Deafness acquired in adult life was not always acquired in the sense that the individual was the subject of a somatic defect. Some forms of otosclerosis were hereditary, and made their appearance during adolescence or adult life. But as in "congenital" deafness, so in "acquired" deafness, the great majority of deaf persons were the subjects of non-inheritable pathological lesions. In childhood tubo-tympanic infections spreading from the nasopharynx were mainly responsible. Meningitis, destroying the internal ear, and infectious disease, giving primary lesions in the middle ear, were responsible for a relatively small group. Syphilis was a declining factor. In adult life deafness was caused by the persistence of nasopharyngeal sepsis as in children, and in addition there was that large and indefinite group of cases named otosclerosis and chronic adhesive middle-ear disease. In old age, nerve deafness, probably caused by auto-intoxications and arterio-sclerosis, was a frequent lesion.

In the treatment of deafness, though success was limited, much could be done for people with middle-ear lesions, but the mainstay of the otologist was prevention. The true hereditary deaf formed a problem in eugenics, the victims of acquired deafness a problem in pathology. The eugenics problem was of considerable magnitude, for it was estimated that in England and Wales alone there are 40,000 deaf-mutes; they and many of their hearing relatives were potential breeders of a much larger group. The problem in pathology resolved itself essentially into the control of infectious diseases, with their rapidly destructive lesions of the internal ear (apart from middle-ear infections) and the eradication of nasopharyngeal sepsis, which led to the dire consequences of chronic septic processes in the middle ear. In this latter connexion the gradual decline in deafness was noteworthy, as due to the extensive organization for the removal of infected tonsils in children. Otorrhoea was a late stage in middle-ear infection; it carried danger not only to hearing but also to life, but modern methods of treatment were effective.

Reviews

BIOPHYSICS

Some degree of specialization is inseparable from the advance of knowledge. Our forebears who interested themselves in the pursuit of natural philosophy would find it difficult to orientate themselves to-day among the various subjects which are the children of their own labours. The process of differentiation still goes on, and we must admit, perhaps with a sigh, that the subject of physiology is following the general trend. Those portions of the subject which are investigated with the aid of exact physical measurements are now often called biophysics. Whether biophysics and biochemistry can now properly be considered to cover the range of what was formerly called physiology, or whether there yet remain some unwanted remnants to which anyone still wishing to call himself a physiologist is very welcome, is a matter for argument. Too often in the past the physiologist has been inadequately informed with regard to pure chemistry and physics. There is now the opposite danger, that biophysicists and biochemists may have but a fragmentary acquaintance with the biological side of their subjects. It is therefore important for us to scrutinize closely any new textbooks and monographs dealing with biophysics, such as the recent *Groundwork of Biophysics*,[1] by Wishart. It should be said at the outset that this book is written by one who has never lost sight of the biological point of view, and who has been engaged in the actual instruction of medical students. If the necessity for the introduction into physiological teaching of so much physical chemistry be conceded, then this book is admittedly excellently suited to the purpose for which it was written. But, excellent though such specialized knowledge may be for the instruction of advanced students in pure science, or future investigators in any biological science, one cannot help wondering whether the medical student's cup is not already more than full. Let us not forget that in a former generation the extravagant expectations held out in the shape of the development of organic chemistry led to the introduction into the medical curriculum of much unwanted and useless matter. It is now recognized, on the one hand, that organic chemistry has actually done immense service to medicine and all the attendant sciences, and, on the other hand, that such advances are matters for the attention of specialists. In the opinion of the reviewer, then, such books as Dr. Wishart's will be of very great service indeed to science students, or such students of medicine as can digest them; for others it is sincerely to be hoped that, since two things cannot be in the same place at the same time, they will not be required to acquire such detailed familiarity with the subject.

Almost simultaneously there appears Professor A. V. Hill's *Adventures in Biophysics*,[2] of which we heartily approve. This is the matter of five lectures delivered in connexion with the opening of the Eldridge Reeves Johnson Foundation for Medical Physics at Philadelphia. We are here taken into the author's confidence and given an opportunity to see the working of his mind upon his problems. It is clear that he thinks logically and quantitatively, but by no means unbiologically. The book will appeal to advanced students and to other investigators, and deals with the advancing fringe of the subject, chiefly

[1] *Groundwork of Biophysics.* By G. M. Wishart, B.Sc., M.D. London: G. Bell and Sons, Ltd. 1931. (Pp. vii + 344; 81 figs. 12s. 6d. net.)

[2] *Adventures in Biophysics.* By A. V. Hill, Sc.D., LL.D., M.D., F.R.S. London: Milford, Oxford University Press. 1931. (Pp. 161 + 161; illustrated. 12s. 6d. net.)

in relation to muscular contraction. Admittedly, to this adept in mathematics and physics, biophysics can be an adventure. We agree with him, and consider it to be often a profitable and delightful one—but not for the inexpert.

SALT IN NEPHRITIS

A most important book, by L. Blum and C. van Caulaert, on the role of salt in nephritis,[1] arouses at first some melancholy reflections since, as the preface states, it has appeared after the death of the senior author, Professor Léon Blum of Strasbourg, and has been completed by his co-workers, van Caulaert and Pétrequin. The work on the physico-chemical problems of renal disease carried out in Strasbourg since the war is remarkable in many ways, and the output of Blum himself and of his pupils has been enormous. The present book gives a connected account of all the physico-chemical studies of salt-retention and salt-depletion in their relation to different types of nephritis, and, what is more, explains clearly the reasons for definite lines of therapeutics which in practice have proved most successful. It is safe to say that Blum's work, highly original in its character, has already made a deep impression on all workers, and is being followed up in many lands. The book is divided into two distinct parts: the first on nephritis with chloride retention (retention chlorurée); the second on nephritis with chloride depletion (hypochloruration).

Blum's work began from the well-known earlier observations of Widal, who divided nephritis into the hydraemic, azotaemic, albuminuric, and hypertensive varieties. It was soon found, however, in partial criticism of Widal's results, that there is not a regular and constant parallelism between retention of sodium chloride and retention of water in cases of nephritis with oedema. Blum's researches showed that the retention of chlorine is often greater than that of sodium, and that the elimination of these two elements from the body may be essentially different. In this way commenced a wide study of the phenomena of water exchange in the tissues, which in its side-tracks has led to eminently practical results. Blum was struck by the experiments of Magnus-Levy (1920) on the occurrence of severe oedema induced by injections of sodium bicarbonate, and he began to wonder whether it was not the retention of sodium rather than chlorine that induced oedema in nephritis. This hypothesis was soon shown to be correct; it is only chloride of *sodium* which, when retained, can induce oedema, and, on the other hand, chlorides of potassium, ammonium, and calcium may have a powerful diuretic effect. This is in brief the history of the introduction of calcium chloride as a diuretic in cases of renal oedema. The importance of chlorine in these problems is, however, fundamental, except as regards oedema, and Blum passes on to consider cases of chloride retention in nephritis without oedema. Such cases were first recognized by Ambard and others in 1905, but Blum and van Caulaert have greatly extended our knowledge of them. Much more work on this problem still remains to be done, but Blum and his colleagues noted that in cases of chloride retention without oedema uraemia is particularly liable to ensue. The views concerning uraemia expressed in this book are highly original and stimulating, but at present are bound to be controversial.

Founded on his views of salt retention, Blum and his colleagues have developed new lines of treatment for cases of nephritis with "hyperchloruration." The main plan is indicated on page 163 of their book, and must be read in full to prevent injustice from a short review. Briefly put, the essential points are: (1) A regime of chloride depletion—a salt-poor diet. (2) The administration of drugs inducing chloride excretion—diuretin has proved the best of these. (3) Alkali therapy in cases of chloride retention *without oedema*, to avoid acidosis and (in Blum's view) uraemia—sodium citrate has proved the best. (4) Elimination of sodium, in cases *with oedema*, by administration of Blum's "interstitial diuretics"—calcium chloride is the best.

Part II of the book concerns nephritis with "hypochloruration," and is largely devoted to proof of the existence of a type of renal disease associated with nitrogen retention (azotaemia), in association with diminution of the salt content of the blood. Clinical observations, animal experiments, and chemical analyses of the blood of such patients are all set forth. The treatment of this syndrome is self-evident, and large doses of salt are given. Warnings of complications, if the treatment is overdone, are indicated. In conclusion, it is shown how these abnormalities in the elimination of sodium and of chlorine can be made the basis of a classification of nephritis, essentially practical in that therapeutic measures are thereby strongly indicated. Such a classification is compared and contrasted with the earlier division of nephritis by Widal into the four varieties already mentioned.

This book must be read by all who are grappling with the many problems of renal function in health and disease.

AN INTRODUCTION TO GYNAECOLOGY

It is a common experience among teachers of gynaecology that the popular treatises are so long and technical that the raw student is overpowered by the erudition of his masters, and it is with diffidence and not enthusiasm that he begins this branch of his medical training. Professor Jeff Miller has therefore written *An Introduction to Gynæcology*[2] for the benefit of students who are starting their gynaecological appointments. His aim has been to present an elementary account of the principles and the theoretical and clinical aspects of gynaecology. Treatment is not considered, for, as he points out, "the treatment of patients is not the business of the junior student." There is much to be said for this point of view. The book consists of some 316 pages, and although this may seem long for the subject dealt with, the material is lucidly expounded and the reading easy. The illustrations are exceptionally good, and have been obtained from well-known works, Schröder's diagrams form an exception, for they compare very unfavourably with the originals. From the scientific aspect the book is admirable. The author gives excellent descriptions of the modern work on the physiology of the ovary, and stresses the importance of the work on the active principles of the anterior lobe of the pituitary gland. We cannot speak too highly of this method of approach to the subject. Routine gynaecology in the Victorian age must have been very dull with its empiricisms and butterfly pessaries, but modern gynaecology is obtaining a strict scientific basis, and students of the future should be encouraged to regard it in this light rather than to think gynaecologically in terms of uterine and pelvic congestion.

The chapter on methods of examination has obviously been written with great care, it is a praiseworthy achievement. Most textbooks of gynaecology might usefully take it as a model for their future editions, for it is of much greater practical value to young students than the accounts usually given. The question of prolapse is dealt with in two separate sections—one on downward displacement of the uterus, the other on vaginal and urethral hernia. The pathology of all forms of prolapse is more conveniently described together, rather than in this way.

[2] *An Introduction to Gynæcology.* By Jeff Miller, M.D. London: H. Kimpton. 1931. (Pp. 227, 117 figures. 21s. net.)

and more attention might have been paid to the pathology of prolapse than Professor Miller has thought fit; use might have been made of Tandler and Halban's diagrams, and the etiology explained on purely anatomical lines. It is doubtful if any branch of gynaecology presents more difficulty to the average student. Endometriosis is described at great length; Sampson's theory has been accepted, although it has many opponents in America at the present time. A noteworthy feature of the book is the omission of any discussion on the so-called chronic metritis and delayed subinvolution of the English school. Goodall's work has been forgotten, and, although the modern work on the ovarian origin of the associated uterine haemorrhages is accepted for some cases, the author feels diffident in placing before young students the somewhat abstruse conceptions which have been recently put forward, because in his belief they are subjects for the experts.

Professor Miller has produced a work which will deservedly become popular, and which will, in this country, be particularly welcomed for its accounts of the physiological and pathological sides of gynaecology.

PATHOLOGY OF THE SKIN

Dr. LEE MCCARTHY'S *Histopathology of Skin Diseases*[5] is the most ambitious work on the pathological side of dermatology that has been published for many years in the English language. The author has made full use of the opportunities afforded him by his position in the world of dermatology, and by the generosity of Mr. Truxton Beale, to produce a book illustrated on a lavish scale. Even to a greater extent than the ordinary textbook on clinical dermatology, a work dealing with the microscopical appearances of the manifold pathological changes occurring in the skin stands or falls by the quality of its illustrations, and we have no hesitation in saying that the volume before us passes this test. Histology is of great importance for the comprehension of the essential differences which underlie the confusing superficial similarities of various diseases of the skin, and in many cases the microscope is the final court of appeal for questions of practical consequence—especially, perhaps, the occurrence of malignant changes in a previously innocent dermatosis. But this decision is often not so difficult to make as to distinguish the finer histological differences between the various forms of chronic inflammatory change in the skin; and it is in this field that workers will find themselves indebted to the author for his excellent illustrations of the microscopical appearances of, for example, the different varieties of lichen, lupus erythematosus, psoriasis, and eczema. Most of the illustrations are made from drawings by M. A. Bessin of Paris, who has a deserved reputation for the faithful delineation of histological appearances. Illustrations made in this way, and checked by a competent histologist, have advantages over photomicrographs, in that without loss of accuracy accidental features may be omitted and stress laid on the essentials of the picture.

Naturally, Dr. McCarthy has paid very considerable attention to the vast quantity of work that has been done on this subject during the last thirty years, and which for the most part is to be collated only by prolonged research. This laborious task he has obviously carried out conscientiously; a valuable feature of his work is the extensive bibliography with which each successive chapter is furnished. We have all been brought up to believe that the epidermis (unlike the cutis) is embryologically derived exclusively from the ectoderm. Recently Frieboes, an investigator whose opinion demands respect, has advanced the idea that it is to some extent derived from the mesoderm. Dr. McCarthy implies that he is inclined to accept these new and almost revolutionary views. It is a pity that he merely whets our appetite by a brief reference to this fundamental matter without entering into any discussion of the subject. Perhaps, however, he would excuse himself by saying that he is concerned primarily with the pathology and not with the embryology of the skin. There is no doubt that the present work will be welcomed by dermatologists in all English-speaking countries, and will become indispensable to every dermatological and pathological library.

[5] *Histopathology of Skin Diseases.* By Lee McCarthy, M.D. London: Henry Kimpton. 1931. (Pp. 513; 251 figures. £5 5s. net.)

CANCER RESEARCH IN DENMARK

Together with the chief of the radiological department of the municipal hospital of Aarhus, Denmark, Dr. C. KREBS, two colleagues, Drs. H. C. RASK-NIELSEN and A. WAGNER, have written in English a monograph entitled *The Origin of Lymphosarcomatosis and its Relation to Other Forms of Leucosis in White Mice.*[6] These workers describe a type of lymphatic tumour in white mice, which occurs principally in animals that have been exposed to large doses of irradiation by *x* rays. The disease can be transmitted experimentally from one generation to another, but only in animals previously exposed to radiation over the whole body surface. Both in the spontaneous and experimental types of the disease the tumours found have been either a form of what is called "lymphadenosis" or else "lymphosarcomatosis" or "leucosarcomatosis." In view of the confused nomenclature in use for all this group of neoplasms the authors suggest the term "lymphomatosis infiltrans" for the special type they have been investigating. The monograph contains very complete protocols of the experimental animals and fifteen pages of beautifully printed illustrations.

SURGERY OF THE NERVOUS SYSTEM

The small book, *Grundzüge der Neurochirurgie,*[7] which forms No. 8 of the series Medizinische Praxis published by Professors Grote, Fromme, and Warnekros, presents in compressed form a very good account of the surgery of the nervous system. The various chapters contain sections on pathogenesis, symptomatology and diagnosis, prognosis, and treatment. Although in the space at the author's disposal no very great detail is possible, the book is important, because it presents very ably an account which we may take to be a summary of the best contemporary German thought. Chapters will be found on head injury, brain tumour and abscess, methods of ventricular puncture, and the taking of spinal pressure readings. The second half of the book is concerned with the peripheral nerves, sympathetic nervous system, and the surgery of pain. Altogether the book accomplishes what it sets out to do, and achieves an exceptionally high level of excellence.

NOTES ON BOOKS

The July instalment of the *Annals of Medical History*[8] contains eight articles, in addition to the third and concluding list of *incunabula* of which the College of Physicians of Philadelphia may be so justly proud, for

[6] *The Origin of Lymphosarcomatosis and its Relation to Other Forms of Leucosis in White Mice.* By Carl Krebs, H. C. Rask-Nielsen, and Aage Wagner. *Acta Radiologica,* Supplementum X. Stockholm: P. A. Norstedt und Söner. 1930. (Pp. 53; 15 plates. Swedish crowns 8.)

[7] *Grundzüge der Neurochirurgie.* Von Professor Dr. med. Walter Lehmann. Medizinische Praxis, Band viii. Dresden und Leipzig: T. Steinkopff. (Pp. xii + 197; 23 figures. *RM.*13·50.)

[8] *Annals of Medical History.* New Series, vol. iii, No. 4, July, 1931. Edited by Francis R. Packard, M.D. New York: Paul B. Hoeber, Inc.; London: Baillière, Tindall and Cox. (Pp. 353–474; illustrated. Subscription in Great Britain, £2 5s. for volume of six numbers.

it shows no fewer than 401 volumes. Dr. A. H. Barkley of Lexington, Kentucky, writes on Dr. Samuel Brown (1769-1830) of that city, who was the first professor of medicine west of the Alleghenies, and is said to have been the first in North America—namely, in 1802—to employ vaccination, though this is usually ascribed to Benjamin Waterhouse in 1800. Brown was also the first to advocate the institution of a National Medical Association. His portrait, which appears as the frontispiece, is that of an able and strong personality. There are two articles dealing with the private papers of great figures in medicine rather more than a century ago: Dr. G. C. Peachey, the historian of St. George's Hospital, appropriately gives a thumb-nail sketch of the life of Matthew Baillie, physician to that hospital, before publishing two of his letters to Dr. Leckie; Miss C. Doris Hellman of New York makes public a diary of Edward Jenner for the years 1810–12. In an interesting essay on tuberculosis and genius Dr. L. J. Moorman gives an account of Francis Thompson, the son of a medical man, an unsuccessful medical student for six years, and author of *The Hound of Heaven*, said to be the finest ode in the English language. The adventures of Nicholas Culpeper, soldier, physician, astrologer, philosopher, and politician, are retailed by Dr. Burton Chance. The foundations of British dermatology are displayed to the reader by Dr. Haldin-Davis; the inventor of the first artificial ice machine (1850), Dr. John Gorrie, is brought to our notice by Dr. Edward Jelks, and Dr. W. W. Anderson gives a brief account of Thomas Holley Chivers, who abandoned medicine to live and die in "the pride of his intellectuality," and was a contemporary and rival of Edgar Allan Poe. Among the readable reviews by Dr. Packard and Dr. David Riesman are those of the recently published lives of W. S. Halsted and J. G. Adami.

Littler's *Elementary Chemistry*[9] has been written primarily as a textbook for students taking the school certificate and matriculation examinations. The author has rightly appreciated the fact that efforts towards condensation tend to defeat themselves, and he has given his subject an illustrative treatment which is both arresting and instructive. It is calculated to lay the foundation of a permanent interest in chemistry. The book fulfils the desired requirements in a manner that cannot fail to be pleasing to the student as well as helpful to the tutor's efforts.

The two major diseases of Egypt are hookworm disease and bilharzia disease. There has accumulated a large quantity of literature on these two subjects, and accurate bibliographies are now essential for their proper study. The Rockefeller Foundation a few years ago issued an extensive list of references to the former; now the Egyptian University has published a *Bibliography of Schistosomiasis* (*Bilharziasis*): *Zoological, Clinical, and Prophylactic*[10] which extends to over 500 pages. The first half of the volume gives an alphabetical list of authors; the second is arranged under subjects, the main headings being general, historical, zoological, clinical, and prevention. The scope of the book is not confined to the two human African species, but is widened to include other species recorded from man and mammals in all parts of the world. The volume, which is very moderately priced, will form an invaluable addition to the library of all who are seriously interested in this subject.

Mr. Arthur Head's beautiful collection of coloured drawings of the fundus has entered upon a new lease of life by the appearance of a second edition of Mr. G. Lindsay Johnson's *Pocket Atlas and Text-Book of the Fundus Oculi*.[11] The preliminary text, which serves as an introduction to the drawings, shows little essential change from the previous edition of 1911, with the exception of the introduction of two chapters, one on cataract and another on the vitreous. It is difficult to understand why these chapters were introduced. That on cataract, for example, although excellent in itself, consists of an elementary discussion of this condition, its causes, and investigation by oblique and reflected illumination, followed by a clinical description of congenital, secondary, traumatic, post-operative, and senile cataract, and dislocation of the lens, all without reference to the subject of the book as indicated by its title. Other matter which is included, such as the description of von Pirquet's cutaneous reaction for tubercle, or of the technique of operations for glaucoma, suggests that the volume is losing its essential character of a fundus atlas. The atlas itself, however, is an excellent one, and its fifty-four plates of the best and most representative of Mr. Head's drawings, each supplied with a clear and informative description, is the most useful of its kind in our literature, with the exception of the classical atlas of Frost. The comparatively small cost should make it a very serviceable reference book for the student and practitioner.

A special number of *Nosokomeion*[12] or Quarterly Hospital Review, has recently been issued, containing the transactions of the second International Hospital Congress, which was held at Vienna from June 8th to 14th. The subjects discussed were: the costs of hospital construction, the ratio of nurses to patients, hospital terminology, hospital legislation, auxiliary hospital activities, the cost of maintenance of patients in hospital, diets in large general hospitals, neurology and psychiatry in the general hospitals, and the influence of health insurance upon hospital practice and dispensaries.

PREPARATIONS AND APPLIANCES

A Portable X-Ray Unit

Watson and Sons (Electro-Medical), Limited (Sunic House, Kingsway) have introduced a portable x-ray unit under the name of the Watson-Sankey. This apparatus is not a small equipment of rigid type, in which everything is sacrificed to compactness, but a series of components which, when assembled, as they can be within a few minutes after arrival in the ward or at the private house, form a complete unit with an output sufficient for all the purposes of ordinary radiography. The components are four in number—namely, the trolley base on which the apparatus is mounted, a high-tension transformer, a box-type switchboard, and a tube stand. The transformer is of the oil-immersed type, with removable high-tension terminals for easy transport. The switchboard carries a milliameter, a voltmeter, two safety fuses, and an adjustable control. The automatic exposure switch is connected to the switchboard by a length of flexible cable, so that the operator is allowed reasonable freedom of movement, and the exposure may be set at anything from 1/4 to 12 seconds by rotating a knob. The tube stand, which is arranged for use with a metalix tube, allows of movement of the tube to any position for radiography, and has sufficient extension for work on either side of the bed. The output is 90 kilovolts peak at 10 milliamperes, and by a special autotransformer it is possible to obtain a range of kilovoltage from 50 upwards. The apparatus is operated on the ordinary power supply, or, if necessary, on the lighting circuit, and arrangements are also made whereby various alternating current voltages may be employed. Special canvas carrying cases are supplied.

Livogen

Livogen (British Drug Houses Ltd.) consists of concentrated liquid extract of liver combined with haemoglobin and vitamin B. The value of liver feeding in secondary anaemias was proved experimentally before the discovery of the specific action of liver and liver extracts in pernicious anaemia. The latter action has proved a comparatively straightforward problem, but the mode of action of liver in secondary anaemias is still very obscure. Liver extracts have been found to be rich in vitamin B_2, and yeast extract has been added to livogen to ensure an adequate content of both vitamins B, and B_2. This combination of active principles is intended to promote blood regeneration in anaemias due to a wide variety of causes, and the makers claim that the preparation is ideal as a general tonic.

British Medical Journal

SATURDAY, OCTOBER 31st, 1931

PROTECTION OF THE CHILD FROM TUBERCULOSIS

It is characteristic of the rapid advance of public health activity in this country, with its increasing concentration on the less obvious sources of danger, that the National Association for the Prevention of Tuberculosis should, at its seventeenth annual congress in Margate this year, have devoted the whole of its attention to considering the problem of tuberculosis in the child. The subject was discussed from various angles, and quite contradictory expressions of opinion were made, which proved frankly puzzling to the lay members of the audience. There was, in particular, a sharp cleavage of opinion on the amount of energy that should be expended on the child during school years. On the one hand, Dr. H. Midgley Turner pleaded that, since there were reasons for believing that about half of the serious tuberculosis in adult life owed its origin to infection in childhood, "the spearhead of the attack on tuberculosis" should be directed against the childhood manifestations of the disease. On the other hand, Dr. L. S. T. Burrell, in an address which was warmly applauded, arguing from the fact that in practice cases of pulmonary tuberculosis in adults rarely gave a history of undue delicacy during childhood, and that the mortality from tuberculosis was lowest in the 5–15 year age group, maintained that under our present conditions we were in danger of paying far too much attention to the school child. The spirit of wisdom of the Margate congress might almost have been purposely distilled by Dr. R. C. Wingfield in the preparation of his address before the Public Health Section of the British Medical Association Meeting at Eastbourne, published in our current issue. Taking as his title "The problem of the child in the tuberculous household," Dr. Wingfield made a critical examination, characterized by the qualities of penetration and level-headedness for which he has acquired a reputation, into the existing state of our knowledge, and the public health attitude towards the subject. It is a paper that should be read carefully by all who were unable to listen to him in person. Instead of commenting on it directly, we shall attempt to draw certain general conclusions, not only from this paper, but from the wide range of papers delivered before the Margate congress.

Before proceeding further let us define our terms. By "latent tuberculosis" we mean a condition in which there are one or more foci of tuberculosis in the body, not severe or extensive enough to give rise to clinically detectable disease. Latent tuberculosis may be subdivided into two types—active and inactive. "Latent active tuberculosis" implies the presence of a lesion in which the tubercle bacilli are actively proliferating; caseation may or may not be present; and the lesion as a whole may progress till it gives rise to clinically manifest symptoms of disease, or it may undergo retrogression with ultimate healing. "Latent inactive tuberculosis" refers to a lesion that is quiescent or that has undergone healing with or without calcification; in case it may be objected that a calcified lesion is of no further importance, let it be remembered that McPhedran and his colleagues have demonstrated by animal inoculation the presence of tubercle bacilli in the tissues surrounding calcified lesions and fibrous apical scars in about 24 per cent. of cases. These are the terms which were used by Burkhardt in his classical investigation at Dresden into the frequency of latent tuberculosis in bodies examined post mortem. The term "latent" comes from the Latin *latēre*, meaning "to be hidden." To restrict it to the sense of "lying dormant" is, we consider, a mistake, because it leaves us with no suitable term for that important type of active lesion which, though often recognizable by *x* rays, is not sufficiently developed to give rise to clinical symptoms of disease; it is, moreover, this type of lesion which we are all anxious to detect. It may be taken that in both these classes the graded intradermal tuberculin test will be positive, and that the sensitivity will probably be higher in the latent active than in the latent inactive type.

The two main problems to be dealt with concern the infant or child in the tuberculous household—briefly referred to as the "contact child"—and the child of school-leaving age. That infants may safely be reared in contact with open tuberculosis is clear from the experience of Papworth, where not one of 133 children born and reared in the settlement has developed clinical tuberculosis. On the other hand, there is evidence that under the usual social conditions the mortality from tuberculosis is appreciably higher in contact than in non-contact children. The procedure to be adopted with these contact children must be determined by the individual circumstances. If the parents are thoroughly intelligent, and strict personal and domestic hygiene can be relied on, there is no reason why the child should not be brought up in the home. If the conditions are adverse, the child may be removed for the first few years of life to a home in the country, as under the Grancher system, or preferably to a home or institution in the town, where it can be brought up under conditions similar to those of non-contact children. This latter method has the advantage that the child is not far from its parents, and enjoys the benefit of being reared in the type of environment in which it will probably have to spend the greater portion of its future life. If the domestic conditions are bad, and if for one reason or another the child cannot be removed from home, the question of vaccination with B.C.G. should be seriously considered. It is for this class of case that the vaccine seems to be most suitable. Experience in New York has shown that if it is given by the intradermal method ill-effects are uncommon,

and the infant usually develops a positive tuberculin reaction.

So far as the child of school-leaving age is concerned, attention should be devoted mainly to the detection of latent active lesions, which, under the more strenuous conditions of office or factory life shortly to be experienced, may possibly progress to the stage of clinical tuberculosis. For this purpose each child, before leaving school, should be tested with tuberculin. The positive reactors should be examined under the *x* rays, and divided as far as possible into the latent active and the latent inactive types. Careful examination of children of the latent active type will probably reveal, according to the experience of Opie and his colleagues in Philadelphia, a small proportion who are in the incipient stage of tuberculosis; these should be sent to a preventorium or sanatorium. The remainder of the latent active type should be supervised by the tuberculosis dispensary, so that early treatment can be adopted immediately any untoward signs develop.

There are still considerable blanks in our knowledge, and not till these are filled in will it be possible to express a sound opinion on the value of certain preventive measures. We have much to learn about the meaning of the development of a positive tuberculin reaction. Is this development to be regarded as a danger signal, or does it represent the incipient stage of immunity and give cause for thankfulness? What proportion of tuberculin-positive and tuberculin-negative reactors in late childhood develop pulmonary tuberculosis during young adult life? Is pulmonary tuberculosis in adult life due to a reinfection of an allergic person (as Opie believes, and as most laboratory work indicates), or is it due to recrudescence of a lesion acquired in childhood? What is the importance of dosage in primary and secondary infections, and what truth is there in Dudley's conception of the velocity of infection? These are simple questions, and the attempt to answer them should be the inspiration of every tuberculosis officer.

BIOLOGICAL STANDARDIZATION

The Permanent Standards Commission of the Health Organization of the League of Nations has now published the report of its last meeting, held in June at the London School of Hygiene and Tropical Medicine.[1] On the preceding days committees of experts had discussed many of the technical problems dealt with in the report, and had submitted definite recommendations for the consideration of the commission. The report now issued states briefly the final form in which these recommendations were presented to, and have been accepted by, the Health Committee of the League. The work of the commission is largely concerned with the problems involved in the standardization of antiserums and other biological substances, and has especially and continually in view the establishment of biological standards, and the definition of units in terms of these standards, for international acceptance and use. Since its formation in 1923, the commission has secured the adoption, by international agreement, of standards and units for diphtheria and tetanus antitoxins, antidysentery serum, insulin, pituitary (posterior lobe) extract, digitalis, salvarsan, and other biological substances of a similar class. These standards and units have received world-wide recognition and acceptance, and the value of a uniform system of notation, unitage, and measurement, both for the treatment and diagnosis of disease and for the prosecution of research, is being increasingly recognized. The present report records the nature of the problems studied, the progress made, and the decisions reached since the last meeting of the commission at Frankfort in 1928, and outlines the questions to be studied in the immediate future.

During the war antitoxins prepared against the toxins of the organisms of the gas-gangrene group were used for the treatment and prophylaxis of wound infections, and these antitoxins are now coming into more general use in the civilian surgical practice of many countries, particularly as a prophylactic measure in abdominal operations. The question of their biological standardization is of growing importance, and past experience has shown that international agreement ought to be achieved before several units, possibly of widely different values, are proposed or accepted in individual countries. As a beginning, the commission has devoted its attention to the establishment of a standard and the definition of a unit for perfringens antitoxin. The committee of experts which investigated the standardization of this antitoxin wisely decided to base the international unit on the only standard which had been proposed when its inquiry began. From the results of its investigations the committee concluded that perfringens antitoxin can be assayed with a high degree of accuracy, and that simple and practicable methods of standardization, which yield consistent results when applied by different workers in different countries, are available. A standard for perfringens antitoxin has accordingly been established, and a unit in terms of the standard has been defined and accepted for international use. Investigations of a similar kind are now to be undertaken with respect to gas-gangrene (*Vibrion septique*) antitoxin.

The investigation of the many problems arising in connexion with diphtheria continues to engage the attention of the commission. Two questions of far-reaching practical importance are to be studied in the immediate future: an inquiry into cases of diphtheria, reported chiefly on the European continent, which have apparently failed to respond to treatment by antitoxin, and an inquiry into the possibility of obtaining international agreement on the standardization of diphtheria prophylactic. International agreement has been reached with regard to the definition and determination of the Schick test dose of diphtheria toxin. Different views have been held as to the method of determining the quantity of diphtheria toxin to be used in this test,

[1] League of Nations. Health Organization. Geneva, 1931. (1s. 6d.)

and these have found expression in official regulations. In some countries the original definition of Schick—one-fiftieth of the minimum lethal dose, for a guinea-pig, of a matured toxin—is held to be sufficient for practical purposes. Other workers, notably Glenny in this country and Kellogg in America, have maintained that, since toxins contain very varying proportions of toxin and toxoid, the level of immunity due to antitoxin in the patient indicated by a given toxin is dependent, not merely on the toxin present in the dose injected, but also on its combining power for antitoxin, and that accordingly, in defining the Schick test dose, the combining power for antitoxin as well as the toxicity should be taken into account. Convincing experimental evidence has been produced in support of these views; what remained in doubt, however, was the necessity of this admittedly more accurate adjustment of the dose for the practical conduct of the Schick test. An extensive trial has therefore been conducted, in which workers in seven different countries have participated. Two Schick test toxins, adjusted to contain the same amounts of toxin in their test doses, but differing rather widely in their combining powers, were tested on nearly 1,500 individuals. The scope of the inquiry, and the results obtained, are given in an appendix to the report. It was demonstrated that the number of persons classed as Schick-positive or Schick-negative depends upon the properties of the toxin used; in the case of the two toxins studied the difference amounted to about 5 per cent. The difference is not large, but it was clearly desirable so to frame an international definition of the Schick test dose as to eliminate it altogether. In this country, and in some others, the international definition now accepted will involve no change in the official regulations; in others, in which the determination of the dose has hitherto been based on the lethal action alone of the toxin, an additional test to control the combining power will be necessary. The Schick test is a most important instrument in the hands of investigators in many countries who are searching for the knowledge which will enable public health authorities to bring the disease under more effective control, and the adoption by international agreement of a uniform practice for determining immunity and susceptibility will be of value in correlating the results obtained in countries widely separated geographically.

A definite advance is recorded in the report with regard to tuberculin. Investigations on the methods of conducting the test, and comparative studies of different international standards of tuberculin, have been in progress for some years, and the commission is now able to state that agreement has been reached for acceptance of a standard tuberculin for international use. This standard, like the antitoxin standards, is preserved at the State Serum Institute, Copenhagen. The activities of the commission are now being extended to include the standardization of those veterinary products whose use affects also human therapeutics, and the standardization of sex hormones. For the former studies the assistance of experts in veterinary medicine will be sought, and Dr. H. H. Dale, director of the National Institute for Medical Research, London, has been asked to organize the co-operation of experts in different countries, with a view to agreements concerning standards for sex hormones.

The Permanent Standards Commission at the same meeting adopted a series of important recommendations submitted by the Conference on Vitamin Standards which was sitting in London at the same time. With this matter we propose to deal in our next issue.

THE PANEL CONFERENCE

The Annual Conference of Representatives of Local Medical and Panel Committees, which was held last week, proved that there was less division of opinion than some had expected on one or two matters of recent controversy. A full report of the proceedings of the Conference will be found in the *Supplement* to our present issue, and it shows that, besides a number of amendments to the Medical Benefit Regulations which were submitted for confirmation or approval, there were three main matters on which decisions had to be taken. The chairman is to be congratulated upon the way in which he conducted what might have been a very difficult meeting, and the members upon the wisdom of the decisions at which they arrived. One of these main decisions had reference to the subject upon which we commented in a leading article a fortnight ago[1]—the cause of the increase in sickness benefit claims during recent years. The Conference unanimously approved the reply which the Insurance Acts Committee had sent to the Ministry of Health as a rejoinder to the Memorandum in which the Ministry had attempted to show that the main factor in this increase was laxity of medical certification. The experience of this large body of representative insurance practitioners enabled them to endorse, without cavil or dissent, the contention that the increased call upon sickness and disablement benefit funds has been due in overwhelming degree to a growth in the number of legitimate claims made by insured persons, and that, of subsidiary causes, improper medical certification was the least probable and the least demonstrable. The complete argument will be found in the *Supplement* to our issue of October 10th (pp. 206–9), and the Conference desired that the document in which it is set out should be distributed at least as widely as was the Memorandum of the Ministry of Health to which it appears to be an unrefutable answer.

The longest discussion at the Conference, however, was directed naturally to the deduction from the capitation fee on the basis of which insurance practitioners are remunerated. There has been a good deal of criticism of the action of the Insurance Acts Committee, both in acquiescing in the original proposal of the Government to reduce the capitation fee by one shilling temporarily, and, when circumstances had changed so

that the matter was reopened, in hesitating to accept on behalf of insurance practitioners the smaller deduction then proposed. There were those who objected to the earlier action having been taken without reference to Panel Committees and insurance practitioners, and there were others who thought that in the later event a prompt acceptance would have been preferable to such reference. Both views had found expression in the correspondence columns of the *Supplement*. The Insurance Acts Committee had in each instance to form its judgement in a very difficult situation. The Conference recognized this, and, by an overwhelming majority, endorsed the action which had been taken. On the immediately practical point of the attitude to be adopted in face of the accomplished fact of the deduction, there was an equally emphatic decision, which the medical profession as a whole will approve. It was recognized that national sacrifice was necessary and that insurance practitioners would endure their part in it in no grudging spirit; but it was placed on record that, in fact, the sacrifice asked from insurance practitioners was larger in proportion than that demanded in other comparable cases, that it should be reconsidered as soon as national circumstances allowed, that the question of the amount of the capitation fee was not raised on its merits, and that therefore a strong protest must be made against the unsubstantiated statement in a paragraph of the Economy Report that the "payments to the doctors are too high." It should be noted that all these points have been allowed by the Minister of Health in his statements or letters, including the final wise communication which he sent to the Conference itself. The sacrifice is a real one: in many individual cases it will be a great one; but the need is also real and great.

The question was once more raised whether the Insurance Acts Committee ought to continue to be recognized as representing centrally insurance practitioners, or whether the constitution of that committee should be altered or reviewed. The pleas that the central committee should have no connexion with the British Medical Association, and that it should be wholly composed of insurance practitioners, and, even so, should not contain any who acted as part-time examining officers for referee purposes, or who served on advisory or inquiry committees in disciplinary cases, were patiently heard and summarily and emphatically rejected. The minority vote came from two or three areas only, and was even smaller than it used to be when such matters appeared regularly on the agenda of the Annual Panel Conference. Apart from other considerations which show the advantage of the present composition of the Insurance Acts Committee—which, though more than three-quarters of its members are insurance practitioners, contains a few representatives of other branches of medical practice—the facts that no doctor is wholly an insurance practitioner, and that ophthalmic surgeons and other members of hospital staffs are intimately concerned with additional treatment benefits and other aspects of the insurance service, show the complete impropriety of the suggestions which were so strikingly repudiated. It is no surprise, though none the less gratifying, that the strenuous attempts in certain interested quarters to create disunion have met with such scant support both at the Annual Conference of Local Medical and Panel Committees and at a similar conference held in Scotland a few days earlier.

It is significant that the Conference once more recorded its protest against the Regulation recently introduced by the late Minister of Health interfering with the free right of an insured person to change his doctor when he wishes, and an appeal may be made to the present Minister to remove this unnecessary disability placed upon insured persons as compared with private patients. In conclusion, we should like to congratulate Dr. H. C. Jonas of Barnstaple upon his election as chairman of the Conference for the ensuing year.

THE RADIUM "BOMB"

In Great Britain the use of radium in making a mass attack on malignant growth has not met with success. Eighteen months ago the four-gram "bomb" was set up in the Westminster Hospital clinic in order that this method of distance irradiation might be thoroughly investigated. In the report of the Radium Commission, printed in our issue of October 17th, it was stated that "the use of the bomb in its present form was not only uneconomic, but unwarranted," and the radium contained in it has accordingly been distributed. It is therefore of particular interest to read at the present moment a treatise by Drs. Max Cheval and Dustin of Brussels concerning their experience during three years of the use of a "bomb" containing the same amount of radium—namely, four grams. The Theory and Practice of Telecurietherapy,[1] as distance irradiation is called on the Continent, deals with every aspect of the method. The first chapter describes in detail, with illustrations, the constitution of the "bomb," the organization of the department, and the theoretical considerations determining the fields of application and dosage. The bomb was so arranged that two patients could be treated at the same time, and Drs. Cheval and Dustin have calculated that with four grams of radium worth eight million Belgian francs (approximately £45,000 sterling) it is possible in one year to treat 130 patients with uterine cancer, each patient receiving 100 treatments. This assumes that the maximum efficiency is attained, patients following one another with perfect regularity night and day. In their second chapter the authors describe their findings on the biological action of the irradiation, including under this heading the effect on the general condition, the normal tissues, and the malignant cells. They have found that patients do not suffer seriously from general injury, and the insignificant degrees of anaemia which they have noticed do not seem to be in accord with the more serious results obtained in this country. Their account of the effect of irradiation on the malignant cells is accompanied by a histological study, illustrated by drawings, and this section occupies more than half

[1] *Théorie et Pratique de la Télé curiethérapie*. Par Max Cheval et A. P. Dustin. Paris: Masson et Cie. 1931. (54 fr.)

the book. It is claimed that this is the first systematic histological study of tumours during the course of their treatment by distance irradiation, and the chapter is concluded by an interesting scientific discussion of the nature of the influence of irradiation on cell division. The final chapter deals with the clinical side of the problem, the clinical material having amounted in three years to 207 patients. Those with cancer of the tongue and upper air passages numbered 47. Two "cures" were obtained among ten patients with carcinoma of the tongue. In the whole category seven "cures" were obtained in 14 "favourable cases"; the remaining 33 were unfavourable. Eight patients with carcinoma of the oesophagus were treated, and of these, two were improved, for eight and twenty-four months respectively. Thirty-six patients with carcinoma of the cervix were treated, twelve "cures" being recorded among the twenty-five favourable cases. Twenty-five patients with carcinoma of the breast were treated, but twenty of these had already had surgical removal performed, so that the results are of little value as evidence, though two good results have been obtained with irradiation alone among four patients. Thirteen patients with carcinoma of the rectum were treated, of whom only one remains alive. Twenty cases of sarcoma were treated, but no conclusions have been formed. The authors make no exaggerated claims for the method, but suggest that in an increasing number of patients a definitive sterilization of tumours may be expected. That it is an efficient palliative for advanced cases has been demonstrated. The whole treatise forms a good and careful account of a relatively unexplored method of treatment. The results so far obtained do not seem to promise any very startling improvement as compared with other lines of attack.

THE VARIOLA-VACCINIA FLOCCULATION TEST

The application of the flocculation test of Gordon to the diagnosis of small-pox has already formed the subject of a report to the Medical Research Council (Special Report Series, No. 143) by Burgess, Craigie, and Tulloch. Their results applied to material from ninety-six different sources—variola minor, varicella, and septic rashes—and left little doubt as to the specificity of the reaction as well as to its utility in the diagnosis of small-pox. Craigie and Tulloch have continued the investigation with a view not only to giving the test a more extended trial, but also to examining more closely its mechanism and the possibility of improving it. Their findings, incorporated in a report to the Medical Research Council (Special Report Series, No. 156), constitute a most valuable addition to our knowledge of immunity in virus infections.[1] The extended application of the test comprised a further 129 specimens, and the results obtained amply confirm the opinion expressed in the earlier report that the reaction is both specific and delicate. The authors also show how the technique of the test can be improved by freeing the antigen from impurities which interfere with the reaction, and indicate the best methods for the preservation of the flocculating serum. But this is not the most interesting portion of the report. Evidence is produced to show that the reaction depends alone on virus and specific antibody, that contaminating organisms play no part in it (as claimed by Schultz and his colleagues), and, further, that a firm union between virus and antibody takes place in the test tube. Briefly, the reaction behaves like other antigen-antibody reactions, which is what one would have expected. The most valuable part of Craigie and Tulloch's work, however, relates to the production of immunity with neutralized virus. They find that vaccinia virus neutralized with antiserum, although unable to provoke a reaction when injected intradermally, can yet be shown to contain active virus when inoculated intra-testicularly. Further, when this neutralized virus is introduced subcutaneously in rabbits, despite the fact that no reaction occurs, a solid immunity to vaccinia virus is evoked. Similar results have been obtained by Rhoads (*Journ. Exper. Med.*, 1931, liii, 185). Even one inoculation of a surprisingly small amount of virus, so treated, proved sufficient to give a solid immunity in rabbits as tested by dermal inoculation, and there is evidence that the sensitized virus, when dried *in vacuo*, is a stable product. Of course, more work is required on this question, and Craigie and Tulloch are commendably cautious in drawing conclusions, but it would seem that it is along these lines, so clearly indicated by their investigations, that the solution of the problem of a safe method of small-pox prophylaxis will be found.

SCIENCE AND PUBLIC AFFAIRS

Some thought-provoking ideas on the subject of science and the State were put forward by the president of the Royal Photographic Society, Mr. Olaf Bloch, F.I.C., in his annual address from the chair of that body on October 20th. The address was a plea that the scientific man should take a greater place in public affairs. Mr. Bloch pointed out how marked had been the reaction of scientific advance upon human life, except in the sphere of political and social organization, which science had left comparatively untouched. The technical man soon discovered that the government of the community, and the administration of its affairs as at present carried on, came under a completely different category from his own work, so that he was inclined to leave politics and economics severely alone. In this he was wrong, for it should be possible at least to attempt to deal with these matters in the calm, abstract, and logical way in which the scientist pursued his work in the laboratory. The aloofness of the scientist from public life, Mr. Bloch believed, was not likely to continue. Production was passing rapidly under the control of science, and distribution was following; the next stage would be scientific control of administration. The displacement of labour by mechanization, improvements in industrial organization, and all the other factors which made possible the production of wealth with increasing ease, were chiefly due to the efforts of train individuals, who would, sooner or later, find themselves compelled to take part in government. Human questions, said Mr. Bloch, were the most difficult of all with which to experiment. The sphere in which scientific control of the human problem had been least advanced was in public and private health, where there was rather greater certainty in the application of known

ledge to affairs. Much of the experimental work in bacteriology, for example, had led to quite definite and unquestionable results, and the method of applying such results to the control of infectious diseases, to operative surgery, to food preservation, and the like, was not too difficult to work out with a fair degree of accuracy. Moreover, in the sphere of health, opposition to innovations was less profound and prolonged, since, generally speaking, passion was scarcely provoked, and vested interests not too severely ruffled. But in general, where the experiment had to take account, not of a new machine or a new industrial method, but of human affairs, advance was much slower, and the mind moved in a more conventional fashion. An enormous social inertia existed, which was a handicap when the material aspects of life were changing as rapidly as at present. Mr. Bloch contrasted, on the one hand, the openness of mind, the critical examination of both new and old ideas, the willingness to accept whatever seemed worthy of acceptance on such examination, often exhibited by writers on scientific and technical subjects, and, on the other hand, the attitude shown often in the same journals towards social, economic, and political change or review. But the first uncertain steps towards a higher standard of health and living had already been taken.

OCCUPATIONAL THERAPY FOR PAYING MENTAL PATIENTS

At a meeting of the Psychological Group of the Medical Women's Federation, held lately at the Lyceum Club, the subjects discussed included the working of the new Mental Treatment Act, difficult and backward girls in a village colony, and the treatment of mild mental disorder by organized occupation. Dr. Elizabeth Casson, describing the work done at her own hospital in Bristol, stressed the vital importance of a regular routine. The majority of her patients have their breakfast in bed, but those who get up for breakfast are occupied in arranging flowers and helping in the house until 10.30, when everybody goes over to the occupation room for an hour or an hour and a half. After their work there the patients go for a walk, do gardening, or—if the weather is wet—have community singing. From 2 to 4 o'clock everybody rests; after tea they walk in the garden for half an hour and then return to the occupation room for an hour before supper. At 8 o'clock those who do not go to bed play community games or do country dancing. Dr. Casson insists also upon the importance of having the occupational therapy department distinct from the nursing department; her patients are taken to the occupation room by the nurses and fetched from it, as children would be taken to or fetched from school, but once inside the department they see no more of the nurse until work is over. To put the occupational therapist under the matron is, in her opinion, as bad as to put the dispenser under the matron. The therapist must be a specialist carrying out the doctor's prescription; if the nurses like to take an interest in the work—as a parent might help a child with his home-work—that is a very good thing, but the work is far too specialized to be successful if carried out by half-trained people. Dr. Casson thinks that it is better for everybody if the nurses confine themselves strictly to the work of nursing. In the same way exercises must be taught by a games mistress. Games, like handicrafts, should be taught from the beginning as if the patients were children; the atmosphere of going back to school is most beneficial therapeutically. Netball has been found one of the best games for mental patients. The idea first occurred to Dr. Casson when she saw the interest aroused in introverted patients by balloons at Christmas. It is, as she says, extremely difficult not to do something about it when a ball is thrown at you. She regards with horror knitting as an occupation for mental patients; it is possible to carry on a complete fantasy system while knitting busily. Even for the acute agitated melancholic a better task is unravelling silk stockings; beautiful purses can be rewoven from the material. She likes soap carving as an early handicraft; it has the advantage of being extraordinarily cheap, as all the soap can be used afterwards. She has also found weaving very successful. It provides rhythm and a graduation of attention; the patients can apply themselves to thinking out patterns, and there is an extraordinary fascination about doing "just another inch." She has found it very useful for improving the gait of hysterics, as they are obliged to use their feet properly on the treadles. Bookbinding is useful for those who want to sit still, as it keeps them constantly on the move, and leather work teaches perseverance. Cane work is too dull, except for the mentally deficient, she says, and raffia is often the resort of those who will not use their minds. It has been objected that private patients would not care to be put to work; to this Dr. Casson's figures are sufficient answer. Of 100 cases on her books, 84 per cent. have been through the occupational therapy department. For ten it was not prescribed; one was aged 6 weeks and two others 79 and 84 years respectively, while seven only stayed an average of five and a half days in the institution. There were, in fact, only six rebels who absolutely refused to do occupational therapy; it is regrettable to record that one of these was a doctor and another a doctor's wife, whose husband stopped her just as she was getting interested.

HUGHLINGS JACKSON

The publication of the first volume of the *Selected Writings of John Hughlings Jackson*[1] fills a long-felt want. Hughlings Jackson's position is unique among neurological teachers, and hitherto his publications have been available, for the most part, only in the journals in which they were originally published. It is a tribute to his originality that his ideas should have been perpetuated for a generation largely by means of verbal tradition. Now, however, a selection of his papers is made readily available. The first volume, which is edited by Dr. James Taylor, with the advice and assistance of Dr. Gordon Holmes and Dr. F. M. R. Walshe, deals with epilepsy and epileptiform convulsions. It contains all Jackson's most important contributions to this subject, including his observations on localized convulsions and on so-called "uncinate fits." Apart from the value of this collection as an

[1] *Selected Writings of John Hughlings Jackson*; for the Guarantors of Brain by James Taylor, M.D., F.R.C.P., with the advice and assistance of Gordon Holmes, M.D., F.R.C.P., and F. M. R. Walshe, M.D., F.R.C.P. Vol. I. London: Hodder and Stoughton, Ltd. 1931. (25s. net.)

expression of Jackson's ideas, it is a rich mine of clinical observations, and should be read not only by those who are interested in neurological principles, but also by all who have to deal with epileptic patients. The second volume is to contain Jackson's more philosophical papers, including those on aphasia.

THE B.C.G. TRIAL AT LÜBECK

On October 12th the trial of Professor Deycke, Professor Klotz, Dr. Altstaedt, and Sister Schutze commenced.[1] The sittings apparently threaten to occupy in all some three or four weeks. It is a little difficult for the English reader, unfamiliar with the procedure of the German courts, to appreciate the atmosphere. The parents and relatives of the 75 dead children and the 178 others who received the B.C.G. vaccine are present in the gallery, and at critical points in the inquiry make loud comments and protests, the accused make appeals to the parents and public in court, a number of distinguished bacteriologists are present, probably as expert witnesses to assist the court, and they cross-examine the accused. The local authority has already paid £17,500 to the parents. The press eagerly seize on the "high points" of the tragic trial, and sympathy is expressed for Professor Deycke, aged 66, "in the evening of life." The Ministry of Health in Berlin was told that animal tests for harmlessness of the vaccine had been carried through at Lubeck—whereas none had been done. Dr. Shwenski of Sofia is alleged to have stated that the news of the deaths of 96 children in Bulgaria in 1927 after inoculation with B.C.G. had been suppressed. In our issue of June 6th we reviewed the history. It does not at the moment appear probable that any new decisive evidence will emerge which can answer the central question—did the avirulent B.C.G. become virulent on culture at Lubeck, or was the human culture which was kept in the laboratory, by a tragic mistake exchanged for, or mixed with, the B.C.G.? By a coincidence a special committee on tuberculosis of the American Veterinary Medical Association has just published its opinion that, by growing B.C.G. upon certain media, by inducing and selecting a certain type of growth, or by dissociation, highly virulent cultures have been obtained by independent investigators.

INFLUENZA IN 1930-31

The recently published August issue of the Monthly Epidemiological Report of the Health Section of the League of Nations contains an instructive account of the prevalence of influenza throughout the world in 1930–31. All the countries in Europe, and also the United States of America, showed a sudden increase of influenza cases during the winter of 1930–31. With the exception, however, of Sweden and the Irish Free State, where the epidemic was more severe than in 1928–29, the severity of the outbreak was distinctly less than that of the last epidemic of 1928–29, and could not be compared with the pandemic of 1918. The epidemic, indeed, was practically confined to Europe and North America, there being no evidence of an outbreak in Japan or Australia. In all the countries affected pneumonia and other complications were remarkable for their rarity. In England and Wales it was found that though the number of influenza cases rose much more rapidly than in 1929, the maximum morbidity and mortality remained well below the figures for that year.

[1] The British Medical Journal, October 17th, p. 712.

The Bradshaw Lecture before the Royal College of Physicians of London will be delivered by Dr. J. S. Fairbairn on Tuesday, November 3rd, at 5 p.m., his subject is "The medical and psychological aspects of gynaecology." Dr. James Collier will deliver the FitzPatrick Lectures on "The development of neurology from the commencement of the nineteenth century to the present time" on November 5th and 10th, at 5 p.m.

Mr. W. Douglas Harmer will deliver the Semon Lecture in the Barnes Hall of the Royal Society of Medicine on Thursday, November 5th, at 5 p.m. His subject is "The relative value of radiotherapy in the treatment of cancers in the upper air passages."

We regret to announce the death, on October 21st, of Constantin Baron von Economo von San Serff, professor at the University of Vienna, head of the institute for investigation of the brain at the University Clinic, and president of the Psychiatric Society of Vienna. Professor Economo is best known for having been the first to give its name to lethargic encephalitis in 1917. His work on this subject has recently been translated into English.

THE GENERAL ELECTION

MEDICAL MEMBERS OF THE NEW PARLIAMENT

The following fifteen medical men have been elected to the House of Commons at the General Election on Tuesday, October 27th:

Dr. J. D. Cooke (C.), Hammersmith (South)
*Dr. W. E. Elliot (C.), Glasgow (Kelvingrove)
*Dr. F. E. Fremantle (C.), Hertford (St. Albans)
*Dr. H. C. Haslam (C.), Lincolnshire (Horncastle).
Dr. G. B. Hillman (C.), Wakefield
Dr. A. B. Howitt (C.), Reading.
*Dr. Joseph Hunter (L.), Dumfries
Sir Henry Jackson (C.), Wandsworth (Central)
Dr. J. W. Leech (C.), Newcastle-upon-Tyne (West)
*Dr. J. H. Morris-Jones (L. Nat.), Denbigh (unopposed)
Dr. W. J. O'Donovan (C.), Stepney (Mile End)
*Dr. A. Salter (Lab.), Bermondsey (West)
*Professor T. Sinclair (C.), Belfast (Queen's) University (unopposed).
*Dr. J. H. Williams (Lab.), Carmarthen (Llanelly)
Dr. J. V. Worthington (Nat. Lab.), Gloucester (Forest of Dean)

* Denotes a member of the late Parliament.

The result of the polling in the University of London election, where Sir Ernest Graham-Little has an official, will be declared on Saturday.

We hope to publish next week the polling figures in all the contested elections in which medical candidates were successful.

The list of medical candidates published last week on page 764 should have included the name of Dr. J. D. Cooke, who has now been returned for Hammersmith (South).

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

FIRST ANNUAL DINNER

The first annual dinner of the British College of Obstetricians and Gynaecologists was held at Grosvenor House, London, on October 23rd, with the president, Professor W BLAIR BELL in the chair. The dinner was preceded by a special meeting of the council for an academic ceremony, when Professor Paul Bar of Paris and Professor Essen-Moller of Lund, Sweden, and Lord Riddell were made Honorary Fellows of the College. The ordinary Fellowship was also conferred upon seven recipients, and seven others were admitted to Membership.

CONFERMENT OF HONORARY FELLOWSHIP

Addressing Professor Paul Bar in French, the PRESIDENT said that his great services to the cause of obstetrics and gynaecology had gained for him the homage of womankind and the admiration of the entire world. To Professor Essen Möller, after a few words in Swedish, he said that those who had visited the beautiful clinic in the quiet mediæval city of Lund had come away enchanted and enriched. To Lord Riddell the president expressed thanks on behalf of the College for much help, and spoke of the many years during which he had devoted time and resources to further the advance of medical science.

The French Ambassador and the Swedish Minister were present at the ceremony, and, addressing them, the president said that science knew no boundaries, and by the conferment of Honorary Fellowship on distinguished men in France and in Sweden the truth of this had been again demonstrated.

The FRENCH AMBASSADOR (M. Fleuriau) returned thanks on behalf of Professor Paul Bar. It was the more fitting, he said, that Professor Paul Bar should have been chosen for this honour, because fifty years ago he had been a student in England. He hoped that his election would further the liaison between the specialists of France and of England.

The SWEDISH MINISTER (Baron Palmstierna) said that this distinction would be greatly appreciated in Sweden, where Professor Essen Moller bore a great name and had created a large school of followers.

The dignified ceremony concluded with the words of exhortation spoken by the president, "*Super ardua consurgamus*."

The dinner which followed was attended by a distinguished company. Among those at the principal table were the French and American Ambassadors and the Swedish Minister, Lord Dawson of Penn, P.R.C.P., Sir Thomas Horder, Bt., Dr. H. B. Brackenbury (Chairman of Council of the British Medical Association), the Dean of Canterbury, and the three newly elected Honorary Fellows.

AFTER DINNER SPEECHES

Sir THOMAS HORDER, in proposing the toast of "The College," said that he had a sincere belief in the reasonableness of its institution. As one who worked in an entirely different sphere of medicine, he believed it was in the interest of the subjects which formed the activities of the College that there should be such an institution for men and women who devoted their lives to these subjects. It was rather strange that such a College had not been formed before. The problems of obstetric medicine were peculiar problems, yet none were of greater significance to the individual and to the State. It had been asked why, if obstetric medicine were segregated in this fashion, ophthalmology, dermatology, laryngology, and other subjects should not be similarly segregated. He thought that argument quite fallacious. He could not believe that the problems relating to a special department dealing with a particular part of the body could be compared for a moment in magnitude to the problems inherent in obstetrics and gynaecology. The latter problems were fundamental, while the study of the eye, of the skin, and of the throat, though important, were not, in his view, fundamental. After all, since they began to think of medicine, had they not considered it in all their studies and examinations as tripartite—medicine, surgery, and obstetrics? Was it only a dream that some day in Great Britain there would be an academy of medicine with these three pillars to support it? And was not that dream a little nearer when it was decided to put obstetrics on a base on which it had never yet been built? The Royal College of Physicians of London had asked the new College to nominate a panel of names for examinerships to the Conjoint Board, and it looked to him as though in the near future the College would be responsible for the conduct entirely of the obstetric examinations of the Board. He was glad to see that the College had opened relations very definitely with the Ministry of Health, and had submitted, in response to specific requests, memorandums on maternal mortality and the administration of anæsthetics in midwifery. These external relations seemed of much importance. Within the last few months the President of the Royal College of Physicians had set up a small committee whose duty it was to see that the College kept in touch with external affairs in so far as these had medical bearings. There was always a tendency for such august bodies to lapse into a state of isolation. This action of his own President had been designed to prevent that occurring, but he was not sure at what precocious stage in the existence of any body that condition might not begin to manifest itself. The present gathering made it evident that the new College had no lack of friends outside its walls. But the success of a new institution did not turn so much upon good fellowship outside as upon loyalty, unanimity, and enthusiasm within. Looking on from outside, he was impressed by the toil which must have been necessary to bring the College into being. For those responsible for this exhibition of activity there was already a reward, and to see the reward of one's labours in one's own day was surely something for which to be grateful. Sir Thomas Horder concluded by naming some of the great obstetricians of the immediate past, including one of them who had lived to see the foundation of the College—namely, Francis Champneys. "The spirits of these men are with us to-night, wishing the College success, increased prestige, and an honourable name amongst the institutions of British medicine."

Professor BLAIR BELL, in reply, said that the foundation of institutions such as the College came about in various ways. Henry VIII, in a spasm of remorse for life taking, granted a life saving Charter to the Royal College of Physicians. The College of Surgeons escaped in 1745 from the thraldom of barber surgery, received its Charter in 1800, and, having obtained permission to examine with other bodies in 1875, subsequently became allied with the Royal College of Physicians when the Conjoint Board was formed. The British College of Obstetricians and Gynaecologists was conceived seven years ago, "tormented by ante natal disturbances for five years" and spontaneously delivered but two years since into the heritage awaiting it from the distant past. The long line of descent of the science and art of this branch of medicine, segregated on special study in Sumerian times —3000 B.C.—was one of particular pride, and the College was the demonstration and admission of its ancient rights. In five thousand years or so it would be a matter of conjecture which of the three Colleges was the oldest.

are better sky lighted, and the neighbouring houses are not obscured by a monstrous block It is pleasing to note that the designers of this building were awarded the medal of the Royal Institute of British Architects Yesterday the doctrine of higher and denser building in our towns was held as part of the orthodox faith of national progress, to day it is regarded with rather more than suspicion, to morrow it will probably be looked upon as little short of high treason

Street Lighting

Some interesting experiments in street lighting were recorded by workers at the National Physical Laboratory In Sheffield and in Leicester installations of different forms of street lighting were set up for a length of nearly half a mile All were arranged so as to give the same average illumination, and each could be switched on independently A number of observers were requested to record their observations Among the definite conclusions reached were that bare lamps are the least attractive form of installation, that any device for shading the lamp which produces absence of appreciation of the distant light sources has a depressing effect, that too low a level for the light is disadvantageous, and that lights on one side of the street are poor Unfortunately, the papers by these observers suffer from a tendency to overdo a new technical jargon New words always spring up as a subject develops, but they should be lucidly explained and their connotation made clear

Transmission of light through fog has been investigated by six researches in the United States No visible light can penetrate a heavy fog If the sun is obscured the most powerful marine and aviation beacons are useless From the standpoint of transmission there is no advantage in filtering out any wave lengths present in light, because each wave length is transmitted independently of all others From the standpoint of visibility there is no advantage in filtering out the blue end of the spectrum It might be conceived that the excess scattering of the shorter wave length would build up a glare about the light source, reduce contrast with the background and diminish visibility This has been tested, and it was found that the visibility of a clear light was not increased by using a red filter

Artificial Illumination

Luckiesh and Moss, of the laboratories of the General Electric Company of the United States, put forward what might be described as an impassioned plea for the wider and greater use of artificial light Their paper was entitled, "Humanitarian foot candles They pointed out that artificial lighting, as an engineering activity, was inaugurated in an era of feeble light sources, when the demand for severe visual work was much less than to day The low levels of illumination acceptable at that time were largely justified by the practical and technical difficulties in the way of obtaining proper lighting in adequate amount Whereas outdoor workers are accustomed to light measured in thousands of foot candles the indoor worker is commonly provided with a few foot candles only, and yet he is expected to work for long hours at tasks requiring continuous and close eye work The authors maintained that much nervous energy is thereby wasted which might be turned to good use, and that the economic advantage thereby accruing would outweigh the cost of extra illumination There is ample evidence that when foot candle levels are increased above those now generally existing, a general increase in production follows

The Netherlands Lighting Committee put forward a plea for the examination of certain new lamps which are designed to flood the rooms of the people not only with visible light, but also with ultra violet rays In view of the fact that these artificial sources of light are being employed on an increasingly large scale for hygienic purposes—and especially now that it is realized that individuals may undergo irradiation during work or play without special supervision by experts—the standard requirements to be met by the lighting intended for this purpose ought to be laid down as soon as possible This is in the interests of the user's health, and also in the interests of the manufacturers, who can take these standards as a guide

THE SOUTH AFRICAN MEDICAL CONGRESS

JOHANNESBURG SEPTEMBER 1931

The twenty fifth South African Medical Congress was opened by the Hon Oswald Pirow K C Minister of Justice, on September 14th in the Johannesburg City Hall This is the fourth Annual Scientific Meeting of the Medical Association of South Africa (British Medical Association), into which the two local associations were fused four years ago Mr Pirow welcomed the invitation to open the congress as a compliment to the sister profession—Law He thought that there was need for consultation among the various professions regarding adequate professional control which was becoming difficult, owing, probably to increasing competition especially in these times of depression He referred in glowing terms to the high standard of medical skill in South Africa As illustrations of medical achievement on the Witwatersrand, he mentioned the splendid work done in silicosis prevention by the Miners Phthisis Bureau the notable contributions of the South African Institute for Medical Research to such national problems as plague malaria, and tuberculosis and the model hygienic conditions under which some quarter of a million uncivilized native labourers on the gold mines were housed and fed

Dr A J Orenstein President of the Federal Council of the Association in inducting the President of the Annual Meeting, Dr Francis Napier expressed the special thanks of the Association to the University of the Witwatersrand for its hospitality in providing accommodation for the meeting The numbers this year were larger than at any previous congress Dr Orenstein has inducted the Presidents of the annual scientific meetings ever since the formation of the combined Association four years ago but never he said, had his pleasure been greater than on this occasion, when he had the privilege of inducting a President from his home city, who had been a personal friend from the time of his arrival in South Africa seventeen years ago

Presidential Address A Plea for a State Medical Service

For his presidential address Dr Napier took as his subject "A plea for a State medical service Medical men, he said, knew very well that their profession was an individualistic one, and rightly, because so much depended on the character and capacity of the individual Though nothing should be allowed to interfere unduly with that individualism, there could be no doubt that it had been allowed to go too far, and many abuses had grown up in spite of the code of ethics of the Medical Association The needs of the public were not adequately met at present The man who got the best medical attention was the poor man, who was admitted free of charge to hospital, and had all the advantages of laboratories and specialist opinion That was ideal x ray installations and specialist opinion should be devised for all sections a comparable system should be devised for all sections of the community The rich man could look after himself and could command the best of attention but even then it was doubtful whether he was as well looked after as the poor man A Government Commission three years ago had recommended the adoption in South Africa of

the panel system. But this would certainly prove a dismal failure in this country. No system of national insurance could meet the needs of the whole community. There was a growing conviction in the profession that a State medical service was the only way out. It would be a godsend to the members of the medical profession, who would be relieved of the feeling that they were making money out of their patients. It would be a blessing to the patient, who would no longer have to worry about how he was going to pay his bill. A State service already existed in the case of preventive medicine—a Government Health Department, consisting of a chief and assistant health officers, pathologists, and inspectors; school medical officers and nurses; municipal health officers and their staffs. A curative service, linked up with our hospital system, could provide for men, women, and children in exactly the same way as the poor man is provided for already. A State service need cost the public no more than at present. The State was the public. Democracy required that the Government carried out what the public wanted. To-day the public paid, and paid very heavily. If the State paid, it would be merely taking the public's money out of a different pocket. He was convinced that State medical services would soon be in vogue the world over. Then why copy here any other service which had proved ineffective elsewhere? It might mean to the profession certain sacrifice of independence and remuneration. But he appealed to his colleagues to remember that the medical profession was one of service, not of money-making.

The Sectional Meetings

A scientific meeting consists of plenary sessions in each of the five Sections—medicine, surgery, gynaecology and obstetrics, public health, and special subjects. At the plenary session of each Section a subject for general discussion is introduced by a paper. The subjects selected all evoked good discussions. They were: constipation, diagnosis and treatment of acute appendicitis, medical attendance in pregnancy and the puerperium, pure milk supply, and hysterical phenomena. On the last-named there was a symposium, the various aspects being introduced by half a dozen specialists. The sectional papers were, on the whole, shorter than in previous years, so that more time was available for discussion. They dealt with a great variety of subjects; local problems bulked largely—typhus fever, amoebiases, solanacapsine (extracted from a local poisonous weed), obstetrics among Bantus, blackwater fever, heat-stroke in gold mines, and radiological practice in South Africa.

The Subsection of Psychiatry held a joint meeting with the Public Health Section on the much-discussed subject of sterilization of the unfit. Professor J. T. Dunston, Union Commissioner for Mental Hygiene, a staunch advocate of such action, introduced the subject in an eloquent and well-reasoned paper. He was strongly opposed by Dr. Egerton Brown, who has recently retired from the Mental Service of the Union.

The plenary session on milk produced an interesting discussion, because of the Natal experiment for eradication of bovine tuberculosis, commenced in Durban some ten months ago. Two months ago the Durban Municipal Council introduced by-laws whereby, in effect, no raw milk can be sold in the borough unless it is derived from tuberculin-tested herds. As some 30 per cent. of all the animals tested were found to react positively, and had either to be destroyed or isolated, the local dairy industry suffered great financial loss.

Social Functions

The social side of the congress was an undoubted success. Visiting members were, as usual, made honorary members of all the important local clubs, including eight golf clubs; the latter, in particular, were well patronized by the visitors, who expressed surprise at the well-kept condition of the courses, in spite of the severely dry and cold high veld winter, which was just drawing to a close. Garden parties were given by the Mayor of Johannesburg and by the President, and members were the guests of the Council and Senate of the Witwatersrand University on the occasion of the conferment of honorary doctorates on the President of Congress, Dr. Napier, and on the Chairman of the Federal Council of the Association, Dr. Orenstein.

Congress Dinner

The official dinner of the congress was held at the Carlton Hotel. When the loyal toasts to the King and Governor-General had been honoured, Dr. Dru Drury proposed "South Africa," to which the Minister of Public Health, Dr. D. F. Malan, replied. Dr. Drury complimented the Government on the passing, after many years of struggle, of the Medical, Dental, and Pharmacy Act. The Minister pointed out that, valuable as this Act was, it should be remembered that it only gave them the machinery; its real purpose was to strengthen their fighting capacity against ill-health. They were still busy merely outlining the task for the future with regard to malaria, plague, tuberculosis, and cancer. Even after completing the programme in regard to these diseases, there was still the great task of attending to predisposing causes of disease by the proper balancing of diets and by improving rural conditions. The suggested abolition of provincial councils would undoubtedly facilitate public health administration by the transfer of hospitals and local health services to the Central Government. The existing divided control had greatly impeded the provision of proper health services. Dr. Malan expressed the gratitude of the Government and himself for the very valuable services rendered by the medical profession, the bulk of whose members were doing an enormous amount of good for the people of this country in a self-sacrificing manner. Whatever dangers lay ahead for the profession, it was still not a trade but a calling, a noble calling, and there was plenty of room for men with ideals.

Colonel Denys Reitz, M.P., proposed the toast of "The Medical Association of South Africa," and Dr. Orenstein, in reply, said that the Medical Association, which was an integral part of a world-wide organization, the British Medical Association, now had 12 Branches, 30 Divisions, and over 1,400 members out of 1,600 practitioners. It was the largest professional organization in the Union. The science of medicine advanced so rapidly and covered so wide a field, that the average busy practitioner could not possibly keep abreast of its progress. Yet he must be familiar with the most important advances if he was to deal fairly with his patient. The Association made it possible for him to keep abreast of these advances at a minimum expenditure of time and energy. The country's outstanding medical problem was the need for early and radical improvement in preventive and curative services in rural and native areas. The present position in regard to both was deplorable. Difference of opinion existed only in method.

The Popular Lecture

"Cancer" was selected as the subject of the popular lecture by Mr. C. F. M. Saint, professor of surgery at the Capetown University. It was delivered in the City Hall to an almost exclusively lay audience. The subject was particularly appropriate, in view of the Cancer Conference convened by the Administrator of the Transvaal for the following week, to discuss, among other matters, the establishment of a National Cancer Institute for the Union of South Africa.

X-RAY AND RADIUM PROTECTION

INTERNATIONAL RECOMMENDATIONS

We print below the recommendations for protection against dangers from *x* rays and radium, as revised by the International X-Ray and Radium Commission at the Third International Congress of Radiology, held in Paris last July. The members representing Great Britain on the Commission are Dr. G. W. C. Kaye and Dr. Stanley Melville.

General Principles

The dangers of over-exposure to *x* rays and radium can be avoided by the provision of adequate protection and suitable working conditions. It is the duty of those in charge of *x*-ray and radium departments to ensure such conditions for their personnel. The known effects to be guarded against are: (*a*) injuries to the superficial tissues; (*b*) derangements of internal organs and changes in the blood.

Working Hours, etc.

The following working hours, etc., are recommended for whole-time *x*-ray and radium workers:

(*a*) Not more than seven working hours a day.
(*b*) Not more than five working days a week. The off days to be spent as much as possible out of doors.
(*c*) Not less than four weeks' holiday a year, preferably consecutively.
(*d*) Whole-time workers in hospital *x*-ray and radium departments should not be called upon for other hospital service.
(*e*) X-ray and particularly radium workers should be systematically submitted, both on entry and subsequently at least twice a year, to expert medical, general, and blood examinations. These examinations will determine the acceptance, refusal, limitation, or termination of such occupation.

General X-Ray Recommendations

X-ray departments should not be situated below ground-floor level.

All rooms, including dark rooms, should be provided with windows affording good natural lighting and ready facilities for admitting sunshine and fresh air whenever possible.

All rooms should be provided with adequate exhaust ventilation capable of renewing the air of the room not less than ten times an hour. Air inlets and outlets should be arranged to afford crosswise ventilation of the room.

All rooms should preferably be decorated in light colours.

A working temperature of about 18° C. (65° F.) is desirable in *x*-ray rooms.

X-ray rooms should be large enough to permit a convenient lay-out of the equipment. A minimum floor area of 250 sq. ft. (25 sq. metres) is recommended for *x*-ray rooms, and 100 sq. ft. (10 sq. metres) for dark rooms. Ceilings should be not less than 11 ft. (3.5 metres) high.

Wherever practicable the *x*-ray generating apparatus should be placed in a separate room from the *x*-ray tube.

X-Ray Protective Recommendations

An *x*-ray operator should on no account expose himself unnecessarily to a direct beam of *x* rays.

An operator should place himself as remote as practicable from the *x*-ray tube.

The *x*-ray tube should be surrounded as completely as possible with protective material of adequate lead equivalent.

The following lead equivalents are recommended under average conditions:

Table I.

X Rays Generated by Peak Voltages Kilovolts	Minimum Equivalent Thickness of Lead Millimetres
Not exceeding 75	1.0
" " 100	1.5
" " 125	2.0
" " 150	2.5
" " 175	3.0
" " 200	4.0
" " 250	6.0
" " 300	9.0
" " 350	12.0
" " 400	15.0

In the case of diagnostic work, the operator should be afforded protection from scattered rays by a screen of a minimum lead equivalent of 1 mm.

In the case of *x*-ray treatment the operator is best stationed completely outside the *x*-ray room behind a protective wall of a minimum lead equivalent of 2 mm. This figure should be correspondingly increased if the protective value of the *x*-ray tube enclosure falls short of the values given in Table I. In such event the remaining walls, floor, and ceiling may also be required to provide supplementary protection for adjacent occupants to an extent depending on the circumstances.

Screening examinations should be conducted as rapidly as possible with minimum intensities and apertures. Palpation with the hand should be reduced to the minimum.

The lead glass of fluorescent screens should have the protective values recommended above.

In the case of screening stands the fluorescent screen should, if necessary, be provided with a protective "surround" so that adequate protection against direct radiation is afforded for all positions of the screen and diaphragm.

Screening stands and couches should provide adequate arrangements for protecting the operator against scattered radiation from the patient.

Inspection windows in screens and walls should have protective lead values equivalent to that of the surrounding screen or wall.

Efficient safeguards should be adopted to avoid the omission of a metal filter in *x*-ray treatment.

Protective gloves, which should be suitably lined with fabric or other material, should have a protective value not less than 1.3 mm. lead throughout both back and front (including fingers and wrist). Protective aprons should have a minimum lead value of 1.2 mm.

Electrical Precautions in X-Ray Rooms

The floor covering of the *x*-ray room should be of insulating material, such as wood, rubber, or linoleum.

Overhead conductors should be not less than 9 ft. (3 metres) from the floor. They should consist of stout metal tubing or other coronaless type of conductor. The associated connecting leads should be of coronaless wire kept taut by suitable rheophores.

Wherever possible earthed guards or earthed sheaths should be provided to shield the more adjacent parts of the high-tension system. The use of *x*-ray equipment having the high-tension circuit completely enclosed in earthed conductors is specially recommended. Unless there are reasons to the contrary, metal parts of the apparatus and room should be efficiently earthed.

The use of quick-acting double-pole circuit breakers is recommended. Over-powered fuses should not be used. If more than one apparatus is operated from a common generator, suitable overhead multi-way switches should be provided.

Some suitable form of kilovoltmeter should be provided to afford a measure of the voltage operating the *x*-ray tube.

Special electrical precautions should be taken in rooms where anaesthetics are used in conjunction with *x* rays.

Film Storage Precautions

The use of non-inflammable *x*-ray films should be encouraged. In the case of inflammable films, suitable precautions should be taken as regards their use and storage. Large stocks should be kept in isolated stores, preferably in a separate building or on the roof.

Radium Protective Recommendations

(*a*) *Radium Salts*

Protection for radium workers is required from the effects of: (*a*) beta rays upon the hands; (*b*) gamma rays upon the internal organs, vascular and reproductive systems.

In order to protect the hands from beta rays radium should be placed, in the first place, on distance. The radium should be manipulated with long-handled forceps and should be carried from place to place in long-handled boxes lined on all sides with at least 1 cm. of lead. All manipulations should be carried out as rapidly as possible.

Radium, when not in use, should be stored in a safe as distant as possible from the personnel. It is recommended

that radium tubes or applicators be inserted into separate lead blocks in the safe, giving a thickness of protective wall amounting to the values given in the following table.

TABLE II.

Maximum Quantity of Radium Element	Thickness of Lead
0·2 grams	8·5 centimetres
0·5 "	10·0 "
1·0 "	11·5 "
2·0 "	13·0 "
5·0 "	15·0 "
10·0 "	17·0 "

A separate room should be provided for the "make-up" of screened tubes and applicators, and this room should only be occupied during such work.

In order to protect the body from the penetrating gamma rays during handling of the radium, a screen of not less than 2·5 cm. of lead should be used, and proximity to the radium should only occur during actual work, and for as short a time as possible.

The measurement room should be a separate room, and it should preferably contain the radium only during its actual measurement.

Nurses and attendants should not remain in the same room as patients undergoing radium treatment with quantities exceeding 1·2 gram.

All unskilled work or work which can be learnt in a short period of time should preferably be carried out by temporary workers, who should be engaged on such work for periods not exceeding six months. This applies especially to nurses and those engaged in "making up" applicators.

Discretion should be exercised in transmitting radium salts by post. In the case of small quantities it is recommended that the container should be lined throughout with lead not less than 3 mm. thick. It is more satisfactory to transport large quantities by hand in a suitably designed carrying case.

(b) *Radium Emanation*

In the manipulation of emanation, protection against the beta and gamma rays has likewise to be provided.

The handling of emanation should be carried out, so far as possible, during its relatively inactive state.

The escape of emanation should be very carefully guarded against, and the room in which it is prepared should be provided with an exhaust fan.

Where emanation is likely to come into direct contact with the fingers, thin rubber gloves should be worn to avoid contamination of the hands with active deposit. Otherwise, the protective measure recommended for radium salts should be carried out.

The pumping room should preferably be contained in a separate building. The room should be provided with a connecting tube from the special room in which the radium is stored in solution. The radium in solution should be heavily screened to protect people working in adjacent rooms. This is preferably done by placing the radium in solution in a lead-lined box, the thickness of lead recommended being according to Table II.

Nova et Vetera

ROUBILIAC, CHESELDEN, AND BELCHIER

A fortunate visit by Mrs. Esdaile to the Royal College of Surgeons of England to examine the portrait busts of English surgeons has resulted in the rehabilitation of the two fine terra-cotta busts of Cheselden and Belchier which now stand in the entrance hall of the building. The two busts had for many years been "skied" on brackets over the entrance to the Council room and the Examiners' room, and were described as plaster casts, for they had been repeatedly painted. Mrs. Esdaile, with the eye of an artist, recognized them as something more worthy, and, obtaining a ladder, industriously picked away nine or ten layers of paint until she found what she expected to find—a terra-cotta basis. Informed of this discovery, the President and Council ordered the busts to be stripped of the paint, and there has resulted two real works of art attributed unhesitatingly to Roubiliac, the master sculptor of his generation in England.

The busts were given to the College by Mr. Lucas on December 24th, 1804. The donor, William Lucas, was elected surgeon to Guy's Hospital in 1773, and retired in 1799. "A clever manipulator and a neat surgeon, but not an anatomist," according to Sir Astley Cooper, "he got £300 a year by bleeding, visited a hundred families, but never made more than £500 per annum." His son succeeded his father as surgeon at Guy's in 1799, and resigned in 1824. "He was neat handed but rash in the extreme, cutting amongst most important parts as if they were only skin, and making us all shudder from apprehension of his opening arteries or committing some other error," says Sir Astley.

William Cheselden (1688–1752) was surgeon to St. Thomas's Hospital from 1718 to 1738, and was also for a short time (1733–38) surgeon to St. George's Hospital, then newly founded. He was a man of many attainments, for he is said to have drawn the plans for old Putney Bridge; he was a friend of Addison, Pope, Mead, and Sir Hans Sloane; he was a first-rate pugilist, and he perfected the operation of lateral lithotomy. He was chosen Sheriff of London on June 24th, 1743, but was allowed to "swear off" on the ground that his estate in lands and goods was not of the value of £1,500. He was a member of the United Company of Barbers and Surgeons, and it was partly due to his action that the Surgeons' Company came into existence and the old alliance of Barbers and Surgeons was dissolved.

John Belchier (1706–85) was a favourite pupil of William Cheselden, and was surgeon to Guy's Hospital (1735–68). In one of his papers read before the Royal Society he proved that madder given with food stains the bones bright red. He was a stout and heavy but active man, of whom the story is told that a patient came to him with a pretended complaint. Belchier assured him there was nothing the matter, and the man clapped a pistol to his breast, demanding money. Belchier offered him two guineas and his gold watch. The patient lowered his pistol to take them, and Belchier immediately knocked him down and sat upon him until assistance came. He was buried in the same vault as Guy in the hospital chapel.

Louis François Roubiliac (or Roubillac) (1695–1762) was born at Lyons, and came to London about 1738. He carved a statue of Handel, which was long one of the glories of the Vauxhall Gardens. About 1740 he was making busts, and among his sitters was Dr. Mead; the busts of Cheselden and Belchier were probably executed about this time. A few years later he was engaged on various funeral monuments, of which perhaps the best known are in Westminster Abbey—the Nightingale monument being probably his last work, for he died on January 11th, 1762. He was buried in the churchyard of St. Martin's-in-the-Fields, poor and in debt. Character rather than beauty seems to have been his aim, and the two busts at the College of Surgeons show this most remarkably now that the disfiguring paint of years has been removed. It is noteworthy, too, that at a time when everyone wore a wig neither Cheselden nor Belchier is represented with one, thus bearing out the statement of Nollekens, whose father was apprenticed to the sculptor, that, "notwithstanding his skill, he was not fond of introducing a wig, and endeavoured to persuade his sitters to take their wigs off. His busts of Pope, Lord Bolingbroke, Martin Folkes, Drs. Mead and Frewin, and numerous others of men of literature are without wigs."

D'ARCY POWER.

Scotland

Glasgow Royal Maternity and Women's Hospital

The Glasgow Royal Maternity and Women's Hospital contains 175 beds, of which 78 are reserved for ante-natal cases, 78 for lying-in cases, and 19—in a separate isolation block—for "suspect" cases; any cases of puerperal sepsis are transferred to the Corporation fever hospitals. This institution claims to be the largest purely maternity hospital in the country, and its fifth annual medical report, covering the twelve months ending December 31st, 1930, has a special interest in that it is the first to be issued after a staff reorganization, which has resulted in the hospital adopting the permanent unit system. The lines suggested by the committee of the Royal Society of Medicine for the unification of maternity hospital reports have been followed as far as possible in constructing the present system. The in-patients are classified in three categories as follows: those who had previously been under ante-natal supervision (1,790); emergency cases (1,934); and those applying for admission without recommendation of any kind (745). Thus, of the total of 4,469 patients treated in the hospital wards, 40 per cent. had been under ante-natal supervision of some kind, 43.2 per cent. were emergency cases, and 16.6 per cent. came without any medical recommendations. The total number of cases treated in the wards of the ante-natal department was 1,579, or 35.3 per cent. of all the indoor patients. The apparent discrepancy between this figure and the total number of cases which had been under ante-natal supervision is due mainly to the direct admission of patients from the ante-natal dispensary to the obstetrical department. During the year under review 9,326 patients were dealt with, 778 being sent to public health hospitals and 4,079 being treated in their own homes, in addition to the 4,469 patients admitted to the wards. In preparing this report Dr. H. R. MacLennan, registrar of the hospital, mentions that 70.1 per cent. of the admissions were abnormal cases, and many were in a state of emergency. He adds that this fact, together with many others, such as the high incidence of rickets in the population which is served by the hospital, indicates the gravity of the type of case, which has to be borne in mind when comparing the incidence of the more serious complications of labour and the maternity and morbidity rates with those of institutions where a lesser measure of abnormality is encountered. The popularity of the ante-natal dispensary is increasing each year, and it now has to be open every weekday.

Chair of Psychology in Edinburgh

The inaugural lecture of the new chair in psychology at Edinburgh University was delivered on October 20th by Professor James Drever, the first occupant of the chair. Professor Drever said that a quarter of a century had elapsed since the George Combe Department of Psychology was established in the University, thanks to the far-sightedness of Professor Pringle-Pattison and Professor Sharpey-Schafer, as well as to the generosity of the George Combe Trustees. During that time the expansion of this subject had been very striking. Psychology was one of the oldest of studies and one of the youngest of sciences, and hardly had a history until towards the end of the nineteenth century. Its beginnings as a definite science might be dated from the establishment of Wundt's laboratory at Leipzig in 1879, although before that time, for more than two thousand years, psychology had been studied and taught by philosophers as an integral part of philosophy. Psychological laboratories had now sprung up everywhere, and in America alone during the next two decades no fewer than thirty psychological departments had come into existence, the first being that established at Johns Hopkins University in 1883. The first professor of psychology was Professor Cattell of the University of Pennsylvania, elected in 1888, who had given the first course in experimental psychology offered to students. This branch of the subject had been developed under the influence of physiology, and the psychological laboratory grew out of the physiological laboratory. The great development of mental testing had been brought about mainly through the work of Galton, and the scarcely less important development of animal psychology had a close contact with the development of zoology. Psychiatry had come in through the study of hypnotic phenomena, and in recent times had led up to what was called psycho-analysis. Three main streams of scientific progress—in physiology, general biology, and psychiatry—had thus united to produce the psychology of to-day. With the development of mental testing and animal psychology, all pretence regarding the employment of introspection had been laid aside. The workers in the field of psychology had been avowedly more interested in the phenomena of the unconscious than in the phenomena of the conscious. This widening of the scope of the science had brought many important changes, and armchair psychology was now a thing of the past, so that the text-books of twenty years ago were to-day largely out of date. The lecturer concluded that although there were different schools of psychology at the present time, they were not antagonistic, as each concerned itself with a special line of investigation.

The Adolescent Deaf

At a meeting of the Scoto-Irish branch of the National College of Teachers of the Deaf, held in Edinburgh on October 18th, Mr. George Wilson, who presided, said that the conditions of life of the adolescent deaf in Scotland were too precarious to allow of further delay in dealing with them. The problem of unemployment in regard to the deaf ought to have been considered ten years ago. If a practical scheme of training for these persons was drawn up, funds could probably be procured from a trust in Glasgow specially devoted to the purpose of helping the deaf, or from the Carnegie Endowment or from the Pilgrim Trust. Deaf boys and girls, eager for employment, were leaving the ordinary schools only to swell the ranks of the unemployed, and the teachers of the deaf in Scotland felt that they could not stand aside and see their former pupils swamped by the present wave of unemployment without offering assistance. A paper, read by Miss Eleanor Page, dealing with agricultural training for the post-school deaf children, described the agricultural and horticultural colleges in Great Britain, as well as the farm schools in France and Germany. She suggested the establishment of farm colonies for the deaf in Scotland, where stock could be reared and where market gardening and the bottling and canning of fruit could be carried out by the deaf community under the supervision of a qualified person, who would control the market and the goods. A special committee was appointed to investigate the possibilities of such a scheme.

Central Midwives Board

At a meeting of the Central Midwives Board for Scotland for the hearing of penal cases, Dr. James Haig Ferguson in the chair, it was reported that a midwife had been found guilty of procuring abortion and sentenced to three years' penal servitude. The secretary was directed to remove her name from the roll of midwives, to cancel her certificate, and to prohibit her from attending women in childbirth in any other capacity (Section 8 of the Midwives (Scotland) Act, 1915).

Bignold Hospital, Wick

The Bignold Hospital Aid Committee, at its last meeting, with Provost Duchart in the chair, intimated that after twenty months' work the debt incurred for extensions to the hospital had been completely paid off. When the aid committee was formed this debt amounted to £2,302, and in addition to paying off this sum the committee had raised a further £1,000, which it was resolved to hand over to the hospital trustees for the benefit of the hospital.

England and Wales

Radcliffe Infirmary: Maternity Department

The Duchess of York opened the new maternity department of the Radcliffe Infirmary, Oxford, on October 22nd. Mr. W. M. Goodenough, honorary treasurer of the Infirmary, in welcoming Her Royal Highness, said that the new home was the first part to be completed of the extensions to the hospital for which they had been appealing for funds during the last three years. They were now not only in possession of this home, but the greater part of the necessary buildings was either under construction or being put in hand. He said that Sir William Morris had not only given the home at a cost of £40,000, but had given to them and to the University Medical School jointly a splendid site at a cost of £100,000. Through their connexion with the Medical School they hoped that the hospital would play a growing part in the increase of medical knowledge. The Regius Professor of Medicine, Sir Farquhar Buzzard, in proposing a vote of thanks to the Duchess of York, said that the first step in an ambitious extension scheme had now been taken, and they anticipated that the hospital of their dreams might not be very far from realization. The relations between the University of Oxford and the Radcliffe Infirmary were of the best kind. While watching the hospital's development with an attention not wholly disinterested, the University saw in the future increasing facilities for the study of those difficult problems which confronted those who sought methods for the prevention and cure of disease. Dr. Stobie, the Mayor of Oxford, welcomed the Duchess of York on behalf of the citizens of Oxford. The new building consists of four stories, with the exception of the main ward block, which has two only. On the ground floor there is a pre-natal clinic with emergency labour ward, sisters' quarters, nurses' lecture room, sitting and dining rooms, and kitchen and maids' dining room. Waiting room accommodation for visitors is also provided. On the first floor are the two main wards, each with provision for twelve beds. The remainder of the floor is occupied by single and two-bed wards, together with the large night nursery, babies' bathroom, room for sick babies, and the necessary service rooms, bathrooms, and store rooms. The rooms for paying patients, isolation rooms, and suite of labour wards, with the necessary service rooms, are situated on the third floor. The fourth floor is devoted to staff rooms, consisting of bedrooms for midwives, nurses, and maids. Open-air sun flats are available above the large wards, with access for beds, and the smaller wards and rooms for paying patients have open-air balconies.

Remuneration of Whole-time Medical Officers: Attitude of L.C.C.

If the recommendation of its General Purposes Committee is adopted, the London County Council will not be represented on the advisory committee constituted in accordance with the recommendations of the conference held in 1929 under the chairmanship of Lord Askwith, to consider the question of the remuneration of whole-time medical officers in public health services. The object of the advisory committee is to consider, upon application being made to it by the Ministry of Health, the British Medical Association, or any association of local authorities which has adopted the recommendations of the conference, or by any individual local authority, the merits of any case in which a local authority proposes to employ an officer at a salary or on conditions not in accordance with the recommendations of the conference, or any difficulties which may arise in the application of the recommendations. It was proposed that the advisory committee should consist of seventeen members, the chairman to be appointed by the Ministry of Health, one member to be appointed by each of various representative local government bodies, including the London County Council, and eight by the British Medical Association. Having regard to the exceptional position of the London County Council in the matter, the committee thinks that it need not be represented. It states that the conditions of the Council's service as regards the medical staff at the County Hall are so different from those existing in most, if not all, other areas throughout England and Wales, that it is difficult to institute a detailed comparison between the recommendations of the conference and what obtains in its service. The rates of pay and conditions of service for the medical staff in the hospitals transferred to the Council under the Local Government Act are generally in accordance with those recommended by the conference, the position of medical superintendents being, in fact, somewhat better, and in mental hospitals, also, they are generally in accord.

Burnley Radium Clinic

A short but comprehensive account of the aims and work of the Radium Clinic at the Victoria Hospital, Burnley, has been compiled by Dr. John H. Watson, director of the clinic, and Mr. H. Lawrie, physicist, in order to make clear to the lay public the nature of the work that is being carried on, the scope for extension, and the need of increased financial support. Full details are given of the way in which radium exercises its therapeutic results, and medical practitioners who are less well informed in these respects will find a certain amount of handy information in it. The clinic has now been working for more than twenty months, and is the only one in the county of Lancaster outside the university cities of Manchester and Liverpool which has been devised and equipped on the lines of the Regaud Clinic in Paris. The methods in use are those which have been standardized for the most part in the pioneer clinics of Paris, London, Stockholm, and Brussels, and about 250 new patients are on the register. There have been about 1,500 daily treatments at the clinic, and strict records have been kept on the lines required by the Radium Commission. The waiting list is about eighty, and the amount of radium possessed is 340 mg. With increased financial support it is hoped to set apart fourteen beds for patients requiring radium treatment, in order that special nursing may be provided.

The Teaching of Science

The Alexander Pedler Lecture, under the joint auspices of the British Science Guild and the University of Durham Philosophical Society, was delivered by Professor Irvine Masson in Armstrong College, Newcastle-on-Tyne, on October 21st. Its title was "Problems in the teaching of science." Professor Masson reviewed, on a national scale, education in pure science as it is carried on at our universities and in schools. He asked: Has the pendulum overswung? Are we teaching too much science? Or teaching science too much? Those who were going to

be lifelong scientists must be given an intensive training; but every science was growing now so quickly that it could no longer be confined within the three-year limit of the undergraduate course. Two more years were needed, and were actually expected of a young man before he was eligible for a first post as a practising scientist. This needed universal recognition.

"To those who are not going to be scientists, we are trying to teach too much and too specially. The figures for the whole country show a great preponderance of honours over pass students, and a great many of these honours specialists do not go on with further training in their science, but turn to school teaching, besides other occupations. These carry into the schools the same exclusive specialization, and a vicious circle is created. It is helped, if not caused, by the higher salaries paid under the Burnham scale to school teachers who are honours graduates. If this were altered, and the universities reformed their pass degree courses, we should get much better balanced teaching in schools; and the whole series of educational sieves through which our young people pass (or are forced) would work naturally. In the schools, especially the secondary schools, exaggerated science teaching goes on on a very large scale from absurdly youthful ages, while other subjects—for example, German—are neglected These things are as bad for the future scientist as they are for all his brothers and sisters. They can be cured by the reforms already mentioned, coupled with a change in the functions of the school certificate and the higher school certificate."

Professor Masson's arguments are buttressed, in an appendix to the printed lecture, by a statistical survey which shows the trend during recent years in the choice of pursuits at the universities and schools of this country.

Correspondence

PAIN IN THE ARM AND A DEAD TOOTH

SIR,—The very interesting communication (*British Medical Journal*, October 24th, p. 749) from Dr. H. W. Hills is important, for it shows, what some of us have long taught, that clinical disturbances associated with "dead teeth" and the like are not always explained by the theory of "sepsis." In fact, this theory is in danger of being sometimes a nuisance, for, when the clinical troubles occur, someone is sure to object to removal of the dead structure, not because "it isn't doing harm" (for it *is*), but because "it isn't septic," or because they "can't see how it is a source of infection."

Of course, clinical observation and sound empirical practice are now made subservient to laboratory-bred theory. That we know. But it is a "clinical fact" that many kinds of pathological trouble in the region of the fifth nerve—a physiological mechanism of emotional expression, be it noted—are linked with disturbances at "unexpected distances," not to be explained by any theory of "sepsis," but which go for good when the "trouble" is put right. Dr. Hills has reminded us of the anatomical basis, but it is to be noted that psychological stresses and shunts are also present, the psychological explanations being afforded by the theories of "somatic resonance" and "organ-jargon." That is another story.

The moral of Dr. Hills's anecdote, as of my comments, is that, when a patient is ill, we should not hesitate to put right all that *is* "wrong" merely because we don't "see" how *this* can explain *that*. And, if we want a theory, as a sign from heaven, there is always the old doctrine of *sympathy*, in many respects a larger and more commodious umbrella than that of "septic foci" and the like, which is no longer so weatherproof as it once was. If in any given case we find out, so far as may be, *all* that is wrong with the patient, and try to put right, so far as is possible, all that is wrong—no matter how slender the apparent connexion with the ostensible complaint—we shall be surprised to find with how many "cures" we become credited, and quite rightly too.—I am, etc.,

London, W.1, Oct. 24th. F. G. CROOKSHANK.

PRIORITY IN NEUROLOGICAL SURGERY

SIR,—The publication of the letter by Mr. Donald Armour, entitled "Priority in neurological surgery," in the *British Medical Journal* (July 25th) has recently come to our attention. May we request you to publish the following reply?

Everyone interested in neurology and the surgery of the nervous system takes pleasure in according to Sir Victor Horsley recognition of his remarkable services to medicine. We have not failed to give recognition to him in his connexion with the division of the sensory root of the Gasserian ganglion. In a paper published in the *Philadelphia Medical Journal* (October 25th, 1902, the history and operation in a case described as "one successful case" are given (Frazier), and a claim is made for the superiority of this operation over complete extirpation of the ganglion. In a paper published by us in the *University of Pennsylvania Medical Bulletin* (December, 1901), and also in the *Philadelphia Medical Journal*, the statement is made (Spiller): "I believe that Horsley is the only one who, before Dr. Frazier, has divided the roots of the trigeminal nerve without removing the ganglion. Horsley avulsed them at their attachment to the pons, and his patient died seven hours after the operation." This quotation refers to the *British Medical Journal* of December 12th, 1891 (p. 1249).

It is our understanding that Horsley became convinced from his investigations that the Gasserian ganglion could not be removed successfully by operation, and that therefore he resorted to division of the sensory root. He did this because no other procedure, in his opinion, was possible. We are not aware that any further reference was made to the surgery of the sensory root after the publication of Horsley's paper before the date of our several publications beginning in 1898. At that time all central operations on the trifacial nerve related to removal of the Gasserian ganglion, and, so far as we know, no reference had appeared by any writer regarding the operation on the sensory root which Horsley had performed in one case.

The ganglion operation at that date was exceedingly grave. The mortality was given by Tiffany as 22.2 per cent., and neurologists referred their cases of tic douloureux to the surgeon with hesitation. It is even probable that the mortality of those less skilful than Tiffany was higher. Having these facts in mind, it was suggested (Spiller), in a paper published in collaboration with Dr. Keen in the *American Journal of the Medical Sciences* (November, 1898), that division of the sensory root of the trifacial nerve would probably give the relief from pain that might be hoped for from the removal of the Gasserian ganglion, and probably would be a less serious operation. In 1898 Horsley's case was not known to us.

At that time the regeneration of peripheral nerves was a matter of dispute on account of the studies of several investigators, and especially of those of Ballance and Stewart, and there was uncertainty as to the possibility of regeneration of the sensory root of the Gasserian ganglion. In order to place the operation of the division of the sensory root on a sound foundation, and to exclude the probability of its regeneration after division, seven specimens of the Gasserian ganglion and its roots, removed from as many dogs on which division of the sensory root had been practised (Frazier), were examined (Spiller), and

it was determined that regeneration of the sensory root was improbable, although the results of these experiments were not entirely conclusive.

One of us (Frazier) has, in his several contributions, repeatedly referred to the universally adopted radical operation for trigeminal neuralgia, and has given Spiller credit for the idea of "purposeful section of the sensory root," for several reasons: (1) because he (Frazier) was not familiar with the article in the *British Medical Journal* of December 12th, 1891; (2) because Spiller first proposed the operation to him (Frazier); (3) because the first series of experimental operations to assure permanence of relief were carried out at the suggestion of Spiller; and (4) because the repeated clinical experiences and contributions from the Neurosurgical Clinic of the University Hospital were largely, if not wholly, responsible for the acceptance of this operation throughout the world as a substitute for removal of the ganglion.

It has been substantiated convincingly by the results of operations performed in the Neurosurgical Clinic of the University Hospital that section of the sensory root is less serious than removal of the Gasserian ganglion as forecast in 1898 (Spiller). There have been 665 sensory root operations performed (Frazier) for major trigeminal neuralgia. The mortality at one time was reported as 0.5 per cent. There have been no deaths in the last 264 operations.—We are, etc.,

CHARLES and FRAZIER, M.D.
Philadelphia, Oct. 1st. WILLIAM sit SPILLER, M.D.

CHILD PSYCHOLOGY

SIR,—I feel sure that Dr. H. Devine, in his letter under the above heading (*British Medical Journal*, October 24th), and referring to the study of psychological medicine in London, has quite unintentionally omitted to mention the invaluable teaching of this subject in the Bethlem Royal Hospital. This hospital was the pioneer of teaching in the subject—even before it was made compulsory in the medical curriculum—and the older psychiatrists (myself among the number) remember with gratitude the special instruction and the practical demonstrations in the wards given by the late Sir George Savage and his successors. This hospital welcomed visitors from abroad, as well as students from all the London hospitals, quite apart from those at Guy's and St. Thomas's, to which the staff were specially attached.

The Bethlem Royal Hospital, although now removed from Lambeth, is still in London (Beckenham), and it has the distinction of being served—as a recognized school of the University—by a highly reputed list of teachers in medical psychology and cognate subjects. For many years it was the only mental hospital in which clinical examinations for the Gaskell prize were permitted to be held, and it still carries on most successfully the teaching of psychiatry for undergraduates and graduates who aim at qualifying for the special diploma now required for the higher posts in the service.—I am, etc.,

ROBERT ARMSTRONG-JONES, M.D.
London, S.W., Oct. 24th. (A Governor of the Bethlem Royal Hospital)

SIR,—May I supplement Dr. Devine's letter in the *Journal* of October 24th, by saying that, in addition to the clinics therein mentioned, there has been for several years past, as part of the Department of Psychological Medicine, a clinic at University College Hospital for persons suffering from mental arrest, retardation, and abnormal development. This clinic is attended by a considerable number of maladjusted children. In addition to the physician in charge it has the services of a qualified assistant and an experienced and fully trained social worker; and it not only affords instructional facilities for the students of the hospital, but it is also attended by students from the London School of Economics, where, I may add, a very comprehensive course of lectures in psychological medicine is given for social science students and workers in mental health.

I fully agree with Dr. Devine that it is most regrettable and quite erroneous to suggest that the teaching in London of psychological medicine and child psychology is neglected. This is far from being the case.—I am, etc.,

University College Hospital, W.C., Oct. 26th. A. F. TREDGOLD.

DOSAGE OF DIPHTHERIA ANTITOXIN

SIR,—All would agree with the interesting point in Dr. J. B. Ellison's letter (October 17th, p. 724)—namely, that it is necessary to maintain the concentration of antitoxin on a level high enough to neutralize completely all *incoming* toxin. A child, aged 4, weighing 2 st. 10 lb., suffering from severe diphtheria, who has received 16,000 units of antitoxin intravenously, will have an immediate content of about 20 units of antitoxin per cubic centimetre of blood; five days later about 5 units. We know from clinical experience that a content in a subject's blood of much less than 5 units of antitoxin per cubic centimetre gives high protection. The Schick-negative subject, with about 1/30 of a unit of antitoxin (always expressed per cubic centimetre of blood) does not suffer from the severe diphtheria under discussion. Schick-negative nurses with 1/30 to 1/10 of a unit are, with impunity, tending patients suffering from the severest attacks. We know also that a subcutaneous or intramuscular prophylactic injection of 500 units of serum immediately stops outbreaks. A child of 8, weighing 25 kilos, would have about 1.2 litres of blood (5 per cent. of body weight); his antitoxin unitage after this prophylactic dose would therefore be about 0.1 at twenty-four hours, 0.3 on the third day, and 0.1 about the sixth.

What amount of toxin is absorbed by the patient described by Dr. Ellison? (By the way, if Dr. Ellison will go through his records, how often will he find an account of membrane continuing to spread for two days after a large intravenous dose of antitoxin, it being assumed that swabs yielded only Klebs-Loeffler bacilli and no profuse streptococci or staphylococci?) From the Baden and Dallas accidents we know that 15 to 30 m.l.d. of toxin injected into a child will cause death in between four to six hours, and from Medellin that 250 m.l.d. will kill a child in twenty-four to sixty hours. It is known that an English laboratory worker (Schick-negative, unitage 1/10) injected about 200 guinea-pig m.l.d. (minimum fatal doses) of toxin into himself. No local or general signs or symptoms followed. Since Dr. Ellison's patient lives for several days after serum treatment is commenced, the total amount of toxin absorbed is probably nearer 30 m.l.d. than the higher figure. But the antitoxin present in the blood of a child, even five days after the intravenous injection, is about 5 units; the membrane is extra-corporeal, and the toxin, before it can attack vital vulnerable cells, must make its way through the superficial tissue, where it will find an overwhelming amount of antitoxin ready to neutralize it immediately.

Are not the watery molecules of the Thames as completely excluded by watertight walls at London Bridge in the Cotswolds—though *our* river has disappeared already at Pangbourne! Nevertheless, Dr. Ellison puts his finger on a baffling problem. We do not clearly understand why membrane is formed. The Medellin record shows clearly that in the throats of the unfortunate children into whom toxin was injected, typical membrane occurred

though no Klebs Loeffler bacilli could be found So far as I can trace, no similar observations were made at Boden or at Dallas and most pathologists would say that membrane can occur only when Klebs Loeffler bacilli are present in the throat The observation must therefore be put on record and accepted with what reserve each pathologist will decide But apart from this we do not understand completely what causes the disappearance of the membrane in the average patient A boy known to be Schick negative complained of a sore throat The clinician saw an early membrane and suggested diphtheria Within twenty four hours the thin pellicle had completely disappeared The boy was given no antitoxin, virulent Klebs Loeffler bacilli were present Yet the antitoxin content of his blood changed from 1/10 on the first day of his very mild indisposition to about thirty times as much in a few days One cannot help saying that his efficient 'active immunity,' and rapid production of his own antitoxin, was the cause of the disappearance of the membrane, but there is no proof that other factors may not have been important Dr Ellison will probably agree on the main issue that the clinician who feels that the results of controlled laboratory experiments have some bearing on clinical medicine will, with austere scientific mind, give one large dose intravenously to his gravely ill patient and know that he cannot do more by specific therapy, most will 'play for safety' by giving also an intramuscular dose those who have convinced themselves that repeated doses save more patients than a single dose, will continue to give repeated doses—they probably do no harm—I am, etc,

October 20th M D, D P H

RHEUMATOID ARTHRITIS

SIR,—I have read with interest the correspondence in reply to "Crippled," whose letter appeared in your issue of October 3rd Dr Kerr Pringle suggests that investigation should be made along the lines of a deficiency of vitamin B On this point I had the pleasure of working under Professor Duncan Graham and Dr A Fletcher of Toronto in 1929 In a large percentage of cases of arthritis deformans, where no focus of infection could be demonstrated, the caecum and colon were found to be atonic and greatly dilated This was demonstrated by *x* rays, following barium enemata These patients were then placed on diets low in carbohydrates and high in vitamins, especially vitamin B, which was given concentrated in yeast and wheat germ Patients who were on the thin side were given adequate diets and the obese received reducing diets while no patients received any medicine Monthly *x* ray examinations were made and marked change was noted in most of the cases the bowel contracting down, haustrations appearing, and peristalsis becoming more active At the same time there was definite improvement in the arthritis, which was most noticeable in the rheumatoid form

Dr John Poynton rightly lays great stress on "local focus" in his letter published on October 10th, but surely the time has come when we must look further afield, especially when the 'old reliables," such as teeth, tonsils, and sinuses are so often apparently healthy In *Recent Advances in the Study of Rheumatism* the authors do not stress the use of a barium enema for investigating obscure cases of arthritis Although they mention early investigation carried out by Fletcher in 1922, no reference is made to the more recent work, an account of which appears in the *American Journal of Medical Sciences* for January, 1930 Is it not a possibility that if the bowel was investigated more carefully we might find some suggestion as to why females are more commonly attacked by rheumatoid arthritis than males?—I am etc,

Edinburgh Oct 17th H L FERRIE M D Toronto

THE BLOOD IN GLANDULAR FEVER

SIR,—Correspondents in the *Journal* in the summer of 1930 supplied evidence that glandular fever is common in London even in adults My experience of the disease is confined to children, in whom diagnosis is easy if seen early Recently I attended five cases in a month, and three were seen early enough to enable me to follow the blood picture and to check previous observations of my own Perhaps a note on this would be a useful appendix to the correspondence referred to

It may be said generally that reaction to infection proceeds according to a plan which may be related to these facts in many invertebrates the only wandering cell is the monocyte, so that reaction is necessarily a pure monocytosis, in the lowest vertebrates (lamprey) the lymphocyte is already available, and the reaction is lymphocytosis reinforced by monocytosis which often predominates, in man, marrow cells (leucocytes) are the predominant white cells in the blood and infection is opposed mainly by leucocytosis which is always reinforced, especially in children, by lymphocytosis and monocytosis before return to normal Differences in the relative duration and intensity of these three processes determine the nature of the blood picture, which in glandular fever is easily followed if we arrange symptoms under days of disease, as follows

(1) Sudden onset with sharp pyrexia headache and flushed face (2) Thickly coated tongue with congestion of fauces, epistaxis or vomiting is common On the first two days there is decided leucocytosis, with disappearance of eosinophils, which are not needed at this stage In short, there is the same neutrophilia with eosinopenia as in sepsis and pneumonia The flushed face with circumoral pallor, coated tongue and congested fauces may suggest scarlet fever The blood film excludes this *because scarlet fever is the great exception, and requires* initial eosinophil as well as neutrophil leucocytosis (3) Stiff neck, followed in a few days by tender enlarged lymphatic glands (4) Blood films show, both in red corpuscles and in white cells, changes which in the latter are somewhat characteristic (5) A rash may or may not appear now or in a few days

About the third day leucocytosis is replaced by marked relative and absolute lymphocytosis, with return of eosinophils beyond normal numbers Now this is what occurs in pneumonia, except that the prolonged leucocytosis is compressed into two days in glandular fever In both, return of the eosinophil marks the onset of lymphocytosis The latter continues with little change except an addition of 1 or 2 per cent of plasma cells, which probably differ from lymphocytes chemically more than cytologically and may be called plasmoid lymphocytes comparable with the iodophil leucocytes in pneumonia Though absent from normal blood, these cells are regular attendants on every lymphocytosis At the same time, the red corpuscles show anisocytosis and polychrome disks among which are some with azure rods, arcs and rings (Cabot rings), and a few showing fine punctate basophilia—in short, evidence of toxic anaemia *In mild cases* there is no great monocytosis and return of blood to normal is uneventful except that anaemia and a few plasma cells disappear rather slowly As there are many mild cases this undistinguished blood picture must be common Yet it may be helpful if one considers the relation to symptoms of its three phases

In cases of moderate severity—which in children means considerable glandular disturbance—the developed monocytosis is attended by a remarkable leucoblastosis which is unique among the infectious diseases of children These leucoblasts appear on the fourth day may reach 6 per cent on the sixth day, and remain in the blood for a

week. These cells are quite pathological, and I have offered evidence[1] that they are really immature monocytes (pre-monocytes) accompanying monocytosis, just as myelocytes accompany leucocytosis. They may appear in the monocytosis of malaria, and should be looked for in glandular fever in adults, in whom they might assist diagnosis. In both cases in which I found them the glands were unusually swollen.

Dr. Cantor[2] suggested that glandular fever has three stages—of invasion, of eruption, and of glandular enlargement; that pyrexia is common to all three; but that in some cases the second stage is exaggerated and the third minimized; in others the second is omitted and the third prolonged. Apparently children belong to the latter group, for only the eldest of my patients, a girl of 13, had a rash. On the fifth day a brisk plasmacytosis had appeared, and in the evening gave the count: eosinophils 1, neutrophils 21, lymphocytes 53, monocytes 10, plasma cells 14. Next day the rash appeared on the body—about ten bright erythematous patches with a few urticarial wheals—disappearing in twenty-four hours. On the eighth day the plasma cells fell to 2 per cent., which is usual from the fourth day onwards. This plasmacytosis included both plasma cells and Türck forms, and the latter may be regarded as plasmoid monocytes, which in small numbers accompany every monocytosis—for example, in typhoid and in malaria. The excess is unusual, but occurs sometimes in German measles, in which I found 13.5 per cent. in a woman on the fourth day from beginning of rash. I have also reported[3] 19 per cent. after an intense rash in scarlet fever. In all these cases excess was associated with considerable irritation of lymphatic glands and of skin.—I am, etc.,

"WHAT IS LIFE?"

SIR,—I venture, though but a humble student of biology and physiology, to ask Professor John Haldane a question arising out of his recent volume on the *Philosophic Basis of Biology*. Where are to be found the mechanistic-minded biologists and physiologists against whose supposed doctrines his argument is directed?

I have some limited personal and reading acquaintance with biologists and physiologists to-day, but know none who hold the particular heresies which Professor Haldane is hunting. The same perplexity was present in my mind when reading his earlier work, *The Sciences and Philosophy*, in which a great part of the argument was directed against "Newtonian principles" which had been superseded at the time the book was published.

Professor Haldane, in his letter in the *British Medical Journal* of October 24th, writes: "If we apply to a living organism the conception of matter we have thereby made it impossible to interpret scientifically the phenomena we are dealing with"; presumably some particular conception of matter is here referred to—matter, for example, as independent and self-determining. But in what quarters are such conceptions of matter now held, and does Professor Haldane consider it vicious to embody among our conceptions of the living organism the conceptions of matter that are current among physicists—Planck, for example—to-day?

The majority of biologists and physiologists appear to devote themselves to the discovery of the behaviour of the living organism in all its aspects, believing, apparently, that the picture of life can only so be painted. Philosophy, on the other hand, appears to consider that it has some special means and powers of discovery above and beyond those of the "working class." What *are* these special powers, and what *is* this philosophy which claims them?—I am, etc.,

Liverpool, Oct. 26th. K. W. MONSARRAT.

VACCINATION AND ECONOMY

SIR,—With all respect I cannot quite agree with Dr. Haldin-Davis as to the small-pox lately prevalent in the country being of the mildest possible variety. I have had 766 cases under my care since March, 1928, at the Orsett Joint Hospital, and although the great majority were trivial, we had at least forty severe cases, including several confluent ones, which, however, fortunately recovered. In 1920 we had a small epidemic of thirty-five cases, of which nine died. The cost of maintaining these cases in hospital must have exceeded the cost of vaccinating many thousands of people, and would have paid the salaries of a large number of public vaccinators. I was on the small-pox ships in the 1894 epidemic, when we had 800 deaths, and I believe a virulent case among an unvaccinated population might easily start another fatal epidemic such as occurred in this town in 1902.—I am, etc.,

Grays, Oct. 25th. S. G. FLOYD, M.D.

TREATMENT OF STREPTOCOCCAL INFECTIONS

SIR,—In common with most other medical men, I have in the past felt a certain helplessness in dealing with acute streptococcal infections. Streptococcal antiserums of the polyvalent variety have been, according to the experience of most practitioners, of little or no value. We have in the past regarded the action of an antiserum as being of value for one particular strain of organism only, and in the case of some serums, such as anti-diphtheritic, this is undoubtedly the correct view.

Recently, however, many men have been using anti-scarlatinal streptococcal serum for a variety of streptococcal lesions. In my own limited experience the results have been so encouraging that I feel justified in bringing this subject to the notice of your readers, in the hope that this serum may be given a more extensive trial. The conditions for which it has been used have in every case shown very definite improvement within forty-eight hours. In the space of a communication such as this I can do little more than enumerate the cases under my observation for which this serum has been used.

Streptococcal puerperal septicaemia, 3 cases.
Streptococcal broncho-pneumonia of influenzal type, 3 cases.
Acute post-influenzal otitis media with extensive cervical adenitis, 3 cases.
Streptococcal skin infections of the erysipelas type, 2 cases.
Acute streptococcal cellulitis with adenitis, 2 cases.

In one of the puerperal septicaemia cases in which the organism cultivated from the blood was a non-haemolytic streptococcus, the results were most dramatic. On admission to hospital the patient was delirious, and having rigors on an average of one every four hours. About forty hours after her first dose of serum her temperature dropped to a moderate figure and the rigors ceased. She became mentally rational, wanted her food, and had in every way improved. She continued to receive doses of serum at daily intervals, requiring in all ten doses of 300,000 units.

In one of the influenzal type pneumonia cases, which was in its third week of the disease when the serum was first given, the prognosis seemed hopeless. The patient's

general condition and temperature began to improve rapidly on the second day after the serum injection, and she made a rapid recovery.

All the other cases made rapid recoveries following employment of this serum, but these two are mentioned as those in which, in my opinion, no factor other than the serum could be responsible for recovery. I fully realize the danger of being carried away by one's enthusiasm *with regard to such a remedy as this, but I feel that it is* so very important that any weapon we possess for combating these grave lung and uterine streptococcal infections should be tried out on a larger scale. It is in the influenzal broncho-pneumonia and streptococcal puerperal cases that I am most anxious for a verdict on the effect of treatment with this serum.—I am, etc.,

Barnstaple, October 19th. S. C. SHAW.

ACHONDROPLASIA AND MENTAL DEFICIENCY

SIR,—As the literature I have read on achondroplasia states that achondroplasiacs are mentally bright, I think perhaps the following brief report may be of interest.

A girl, aged 8½, was referred from school regarding her mental condition, the teacher reporting that the child's attainments were only equal to those of a normal child of 5. The girl was an achondroplasiac, and she was also found to be feeble-minded, her speech being defective, her attention somewhat difficult to fix, and her mental age being about 5½ years as tested by the Stanford revision of the Binet-Simon tests.

The mother reported that the child had not started to talk until about 3½ years old. The only point of interest in the personal or family history was the fact that the mother was 50 years of age when the child was born. This suggests that there was perhaps a failure of the mother's reproductive powers affecting the child's development in two directions—mental and physical.—I am, etc.,

Salford, Oct. 15th. H. HEATHCOTE.

USES AND ABUSES OF VACCINES

SIR,—With reference to the article on the uses and abuses of vaccines by Dr. Braxton Hicks, in your issue of October 10th, I should like to corroborate his remarks.

I, and my father before me, have been preparing autogenous vaccines for well over twenty years, with excellent results in a number of conditions. For a very long time I have realized that there was no such thing as a calculable initial dose of vaccine for a given individual, and I adopted a system of *initial subminimal doses*, given at short but gradually increasing intervals, as is suggested by Dr. Braxton Hicks. My doses also increased in strength with the increasing interval, and I can testify that vaccines given by such methods rarely, if ever, cause reactions. The whole secret is to start with few enough organisms, and I often employ only about one-fifth, or even less, of the generally accepted dosage at the outset.

I am astounded by the frequency with which one hears of vaccines (prepared by men whose names are often well to the fore) which have produced serious reactions in the patients to whom the first dose was administered as directed. *There is absolutely no excuse for this.* The policy of *festina lente* produces results which are definitely better than those obtained from excessive initial dosage; moreover, reaction is almost unheard of if the careful procedure is adopted. Much harm has been done to vaccine therapy by these "*high explosive*" vaccines. A patient of one of my colleagues had been treated with vaccine for bronchial asthma at a great London hospital. He was so ill after each injection that the treatment was abandoned, but he was given the vaccine to take to his own private doctor. I was consulted in the matter, and I diluted the vaccine about five times, after which it was given to the patient without any subsequent reaction, but with most marked benefit. One could quote scores of similar instances.

May I, in conclusion, point out the fallacy of putting up autogenous vaccines in rubber-capped bottles, unless two or three different strengths are issued? One can hardly measure less than 0.1 c.cm. of vaccine in a syringe. Now if 0.1 c.cm. of such vaccine contains a *safe initial dose*, the final dose in any reasonable amount of fluid would be far too small. Conversely, if the final dose is to be strong enough, 0.1 c.cm. would contain a dangerous amount of antigen. Autogenous vaccines should always be issued as complete doses in sealed ampoules, preferably bearing numbers as the means of indicating the order in which the injections are to be given.—I am, etc.,

Camberwell, Oct. 22nd. GUY BOUSFIELD.

CO_2 INHALATION FOR ASPHYXIA

SIR,—The original research work of Professor Yandell Henderson of Yale University, which has proved the great value of inhalation of CO_2 in cases of asphyxia, will no doubt be the means of saving many lives. This method was employed empirically hundreds of years ago for the purpose of resuscitating the newborn infant. When the attendant midwife applied her lips to the infant's nostrils and forced CO_2 and oxygen into the lungs, one must suppose that tradition and experience had dictated this method of stimulating the respiratory function. Doubtless that crude method of supplying CO_2 and oxygen was often of service. It might now be used with more confidence in emergency. Eventually, no doubt, all doctors will possess the necessary apparatus for the scientific and accurate application of CO_2 and oxygen.—I am, etc.,

Tottenham, Oct. 21st. BERNARD ROWLANDS.

Medico-Legal

MINERS' NYSTAGMUS: A QUESTION OF COMPENSATION

In the House of Lords, on October 19th, judgement was given in the appeal of Connor *v.* Cadzow Coal Company, Limited, from the Court of Session in Scotland.

The appellant, a miner who had been in the employment of the company, was, in the early part of 1928, disabled by miners' nystagmus. Liability was admitted, and compensation paid on the finding of total incapacity. Afterwards the appellant was certified fit for surface work, and was paid compensation on the footing of partial incapacity and in September, 1929, he was certified to have recovered from the attack and to be fit for ordinary work, whereupon the company ceased to pay compensation, and asked the arbitrator who had determined the case under the Workmen's Compensation Act to end the award of compensation as from that date. The appellant, in reply to this, made certain averments—namely, that he was not able to earn full wages and had not ceased to be incapacitated as a result of the attack, having failed, in consequence of his disability, to obtain employment and that it was admitted in the industry that a workman who had suffered from miners' nystagmus was even though certified as recovered, precluded from entering employment underground, so that his scope of employment and earning capacity had been diminished.

The Court of Session held that the arbitrator was bound to end the right to compensation on the date stated, on the

ground that the certificate of the medical referee indicated complete recovery On coming before the House of Lords, however, the case was remitted to ascertain whether the medical referee had intended to certify that the man had completely recovered in the sense that he was not, in consequence of the attack, more susceptible to the disease than before The referee replied that his certificate was not intended to bear that construction It was therefore agreed by the House of Lords that the certificate must be taken as meaning that the workman was now more susceptible to the disease than before the attack, and formal judgement was pronounced allowing the appeal against the Court of Session, and upholding the arbitrator in his refusal to end the right to compensation

Lord Buckmaster, in delivering the judgement, said that miners' nystagmus was a disease to which men working underground were liable in varying degrees of susceptibility Some appeared to be immune, others were not so fortunate, and fear of the unknown susceptibility had led mine-owners to require a statement as a condition precedent to employment that the man had not suffered from the illness If there was complete recovery after attack, any subsequent attack must be due to the original susceptibility, but if recovery was not complete a recurrence was more probable owing to the fact that the original conditions caused by the first attack had not entirely passed away The certificate in the present case, after further inquiry of the referee, had been found not to have the effect attributed to it by the Court of Session—namely as establishing complete recovery—and [illegible] occurs some in the question whether, after the ordinary symptoms disappeared, and recovery seemed to have taken place, 5 per cent might not still be the fact that exposure to the same conditions would cause the illness immediately to recur Intense judgement of their lordships the fact of complete recovery had not been established in the present case, and the appellant succeeded

The Services

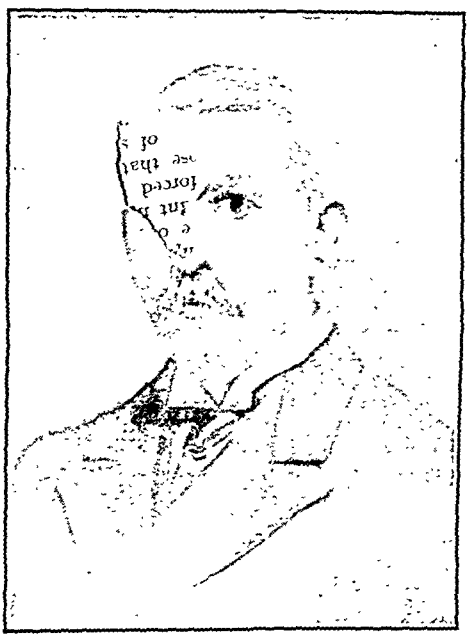
Major F M Collins, M B, F R C S, R A M C, has been appointed surgeon to the Viceroy of India

DEATHS IN THE SERVICES

Major General Lawrence Humphry, C B, C M G, late of the R A M C, and of Stede Court, Biddenden Kent, died at Quetta on October 5th, aged 56 He was born on August 30th, 1875, the son of Mr F A Humphry, was educated at Guy's, and took the M R C S and L R C P Lond in 1899 Entering the R A M C as lieutenant on January 28th, 1899 he became lieutenant colonel in the long war promotion list of March 1st, 1915, brevet colonel on June 3rd 1919 colonel in 1924, and major general on December 20th, 1927, when he was appointed D D M S of the Western Command in India with headquarters at Quetta He served in South Africa for three years 1899-1902, taking part in operations in the Orange River Colony and in Cape Colony, and received the Queen's medal and King's medal, with two clasps to each He also served throughout the war of 1914-18, when from 1917 to 1919 he was A D M S of the 40th Division in France was mentioned in dispatches three times, in the *London Gazette* of November 5th, 1915, July 13th, 1916, and May 25th 1918, and received the C M G in 1916, and a brevet colonelcy in 1919 On November 24th, 1927, he was appointed an honorary surgeon to the Viceroy, and received the C B on January 1st 1931 In 1908 he married Phyllis, daughter of Dr Wat[illegible] Griffin of Crowborough

Surgeon Captain Ramsey Martyn Richards, R N (ret.) of Betworth, Exmouth, died after an operation on September 4th, aged 56 He took the M R C S and L R C P Lond in 1898, entered the Navy soon after, attained the rank of surgeon commander on May 13th, 1912 and retired with an honorary step of rank on October 15th 1924 He served throughout the war of *1914-18*

Surgeon Lieutenant Harry Lee Duncan R N, was drowned at Kinkiang, on the Yangtzekiang River, on September 8th He was educated at Aberdeen, where he took the M B, Ch B in 1922, and entered the Navy on July 2nd 1923 He served for some time in the Mediterranean on H M S *Iron Duke* an aircraft carrier, but at the time of his death was serving on the gunboat *Mantis*



Obituary

SIR MARRIOTT COOKE, K.B.E., M.B.

Late Commissioner of the Board of Control

Sir Marriott Cooke, whose death in his eightieth year took place at his home in London on October 17th, constituted a link between mid-Victorian psychiatry and all that the Mental Treatment Act stands for in our time.

The elder of the two children of Henry Edward Cooke of Harrow, Edward Marriott Cooke was born in 1852. Educated privately at Southampton and at Highgate School, he matriculated in 1869 at the University of London, entered in the same year upon his medical curriculum at King's College, and completed his clinical studies at King's College Hospital. During his undergraduate years he resided in college, the benefit of which he in later life always extolled. Before leaving college he held the post of assistant demonstrator in anatomy. Cooke did not enter the medical profession with any preconceived idea of devoting himself to psychiatry; indeed, so soon as his thoughts began to direct themselves as to the line, general practice or one of the special branches of the profession, which he would like to pursue, it was towards obstetrics and gynaecology that he felt attracted. Whether this attraction grew out of the duties attached to the post of assistant house-accoucheur and of resident accoucheur, which he held at King's College Hospital, cannot now be determined. Upon his own testimony it is, however, certain that when he obtained the post of junior assistant medical officer at the Worcester County and City Mental Hospital at Powick, it was avowedly with the object, while gaining useful experience, of doing some hard reading and of proceeding to some of the higher professional qualifications. He had already passed his primary F.R.C.S. examination, and, having obtained the M.R.C.S. in 1874, he was due to sit for his Final M.B. examination; this he passed in 1877. In those days there was a separate examination for the B.S.; but neither to this degree nor to any further examinations did Cooke ever proceed. Professional or scientific reading was not the relaxation to him which it is to some persons. Not that his practical rather than scientific bent of mind implied any failure to keep in touch with medical progress; on the contrary, he was a regular reader of medical journals, and later on in professional life, although he did not himself prosecute laboratory or other allied work, he gave full scope and encouragement to his junior colleagues, and felt a right pride in any attainments they made in those directions. Probably from this side of his character may be explained the fact that, so far as contributions to medical literature were concerned, writing of that nature was always an effort to him, and that his only contribution to any medical journal was a paper read at the quarterly meeting of the Royal Medico-Psychological Association held at Powick in 1895, and entitled "A review of the last twenty years at the Worcester County and City Lunatic Asylum, with some conclusions derived therefrom." Four years previously, upon his election as president of the Worcester and Hereford Branch of the British Medical Association, he delivered an address on "Some points connected with the causation of mental disease." On the other hand, his official writings, whether reports to visiting committees of mental hospitals, or entries, reports, and minutes arising out of his work later on as a Commissioner, are all remarkable for their lucidity, logical coherence, nicety in choice of words and phrasing, for their exact adherence to fact with an absence of anything savouring of exaggeration, and for the feeling always conveyed in them that the matter in question had been the subject of careful deliberation. Nor, when some recommendation seemed called for, did they ever fail to make quite clear what opinion he had formed and what was the advice which he tendered. Moreover, once this position had been attained there would be no receding from it.

On joining at Powick, Cooke had as his chief Dr. James Sherlock, a man of high medical attainments and of peculiarly suave, courtly, and attractive manner. He it was who, in 1858, had proposed as president of the Medico-Psychological Association for the ensuing year the name of Sir Charles Hastings of Worcester, whose foundation of the British Medical Association is, in part, to be celebrated next year by a pilgrimage to Worcester. Very swiftly Cooke's interest was aroused in the treatment of mental disorders, in the welfare of the insane, and the need of vigilance for their protection—an interest that deepened throughout his life. He not less swiftly recognized, however, that there was room for improvements, among the earliest of which he had in mind being the better supervision of the patients by night. Shortly after he had become the senior of the two assistants, and after he had decided to devote himself to mental hospital work, serious illness befell his chief. Not only did he find himself called upon to act as superintendent for a period of several months, but it also devolved upon him to visit, on behalf of the committee, a number of mental hospitals in order to collect information and to frame a report for its consideration. Despite his short experience, Cooke acquitted himself well; he won high credit both for his management of the institution and for his grip of its future necessities. His outstanding capacity was acknowledged, added to which he possessed good looks and a commanding presence. In 1877 he became superintendent at the Wilts County Mental Hospital, Devizes. In 1881 Dr. Sherlock died suddenly, and Cooke was unanimously appointed to succeed him as medical officer and superintendent at Powick Mental Hospital. For the ensuing seventeen years, with single mind and no thought of still further promotion, the whole of Cooke's energies were devoted to the administration of his hospital and to the welfare of its patients and staff. Throughout these years at Powick he was busily engaged in thinking out and in effecting improvements in his hospital; also in tasks connected with the necessity of its enlargement, as the

result of which its accommodation rose from 770 beds at the time he rejoined as superintendent in 1881 to 1,100 at the time of his appointment, in 1898, as Commissioner in Lunacy. He had a strong conviction of the value of occupation, and claimed that fully 70 per cent. of his patients were usefully employed in one way or another. It was often Cooke's lament, later on as a Commissioner, that in these matters of occupation, of amenities and comforts in the wards, of amusements, of the maintenance of a good band and a well-trained choir, many mental hospitals are not so enthusiastic as they once were. At the end of sixteen years as superintendent at Powick Cooke's strenuous efforts on behalf of his hospital and its patients, and the resultant high standard of efficiency, were rewarded. The Committee of Visitors, upon their own initiative, decided to add £300 a year to his salary, and passed a resolution in which they added a rider to the effect that they wished thus to testify that, in their opinion, they possessed a superintendent second to none in the Kingdom. As this signal mark of favour was publicly announced, it cannot have occasioned surprise when the post of Commissioner in Lunacy, vacant early in 1898 by the death of Dr. J. A. Wallis, was offered to Dr. Cooke.

It is less easy to indicate Cooke's work and views as a Commissioner than as a superintendent, because so much of it all, in his case, is innominate and merged in the Board's corporate activities. Cooke was not an innovator: he preferred to abide by the well-tried measures and arrangements upon which his matured experience had taught him to rely. He was, however, immediately interested in any new suggestion which might advance the treatment of mental disorder, and, if often enough benevolently sceptical as to its ultimate value, he was always ready to encourage its trial. In April, 1914, along with the other members of the Lunacy Commission, he became a Commissioner of the Board of Control, under the provisions of the Mental Deficiency Act of the previous year. Then came the war and the Board's initiation of "The Asylum War-Hospital Scheme," to carry which into effect, and, with the help of the local authorities, to develop it, Cooke's whole-time services, along with those of one of his colleagues, were lent to the War Office from March, 1915, to November, 1916. Under this scheme, twenty-four well-equipped war hospitals, providing over 31,000 beds, were arranged; and there were treated in these hospitals some 480,000 cases. For a man aged 63, Cooke's enthusiasm and energy in connexion with this scheme were remarkable, as were his resourcefulness and fertility of suggestion. From November, 1916, to July, 1918, Cooke acted as chairman of the Board of Control; during the time the then chairman, Sir William Byrne, served as Under Secretary to the Lord Lieutenant of Ireland.

It was in 1918 that, for his war services, as well as for forty-three years spent in the service of the public and as a Commissioner, he was created a K.B.E. Sir Marriott Cooke resigned in August, 1921, and on the following day the King appointed him an Honorary Commissioner. He continued regularly to attend meetings of the Board, as well as to pay occasional official visits, up to the coming into operation, on January 1st, 1931, of the Mental Treatment Act, under which authority for the appointment of honorary members of the Board ceased to exist. In that month his colleagues entertained him to dinner in order to mark both the affectionate esteem in which they had held him, and their sense of his devotion to the cause of those suffering from mental disorder, during his long period of public service, which had extended to fifty-six years.

H. B.

THE LATE DR. MANWARING-WHITE

A correspondent in Lancashire writes: With your permission I would add a few words to the obituary notice of the late Dr. R. Manwaring-White, published in the *Journal* of October 24th. He was one of those men whom one can hardly imagine outside the ranks of the medical profession, so fitted he was by temperament and character for the services which the public needs in illhealth. He had the type of mind that is satisfied by nothing less than an exact diagnosis, and his surgical work, which was his chief interest, was technically skilful, and always careful and judicious. Above all, he was devoted to the needs of his patients, and his real pleasure in life was that of fulfilling those needs. Reference is made in your notice to his critical attitude in matters of medical politics, and I think that the remark is a true one, but in the twenty-five years I knew him I never heard him criticize adversely the conduct of an individual. He was a man of definite opinions, but his charity and patience seemed to his friends inexhaustible, and this, I think, was the chief characteristic of his work and life.

The death of Mrs. MARGARET LAMONT (née Margaret Traill Christie) at Port Said last August, following an operation for acute appendicitis, brought to an end a life of very varied experience. After a brilliant student career at Bedford College and the London (Royal Free Hospital) School of Medicine for Women she graduated M.B., B.S. of the University of London in 1895. In the following year she went to India on special plague duty, and later took charge of the Dufferin Hospital at Calcutta; it was while there that she married and was received into the Roman Catholic Church. She obtained the M.D.Lond. degree in 1897, and also the Cambridge D.P.H. After some wanderings Dr. Lamont settled in Shanghai, and recently her home was in Durban, where her two married daughters now reside. The subject of medical missions always occupied the chief place in her interests, and it was when travelling for this cause that she was overtaken by her last illness.

Medical News

The twelfth Maudsley Lecture will be delivered before the Royal Medico-Psychological Association by Sir Hubert Bond in the Great Hall of the British Medical Association House, Tavistock Square, on Tuesday, November 24th, at 3 p.m. Psychiatrists and other medical practitioners, psychologists, and members of the legal profession, teachers and students, and all interested in mental welfare are cordially invited. Admission without ticket.

The annual dinner of past and present students of the Leeds School of Medicine will be held in the Hotel Metropole, Leeds, on Thursday, November 12th, at 6.30 for 7 o'clock, under the presidency of Dr. G. B. Hillman.

At the meeting of the Pharmaceutical Society of Great Britain, to be held at 17, Bloomsbury Square, W.C., on Tuesday, November 10th, an address will be given by Sir William Willcox on "The practical relationship of bacteriology to pharmacy, and its influence on the curriculum." The president will take the chair at 8.30 p.m.

At the meeting of the Medical Society of Individual Psychology to be held on November 12th Dr. Yates Pearson will speak on individual psychology of [illegible]. On December 10th Dr. F. G. Crookshank will [illegible] physical findings in psychological neurosis. The annual dinner of the society has been arranged for January [illegible], 1932, and further meetings will be held at 11, Chandos Street, W., on the second Thursday of each month [illegible] July.

A meeting of the Metropolitan Branch of the Society of Medical Officers of Health will be held at Milborne St. Andrew, Blandford, Dorset, on Thursday, November 5th, at 12.30 p.m., when the Bladen Dairies will be inspected, at the invitation of Sir Ernest Debenham.

At a meeting of the Royal Sanitary Institute to be held at 90, Buckingham Palace Road, S.W., on Tuesday, November 10th, at 6 p.m., a discussion on "The London County Council Drainage By-laws" will be opened by Dr. William Butler, Medical Officer, General Purposes, London County Council.

The Fellowship of Medicine and Post-Graduate Medical Association announces that the following special courses will begin on November 2nd: proctology at Gordon Hospital for one week, with afternoon clinics (fee £1 1s.); medicine, surgery, and gynaecology at the Royal Waterloo Hospital for three weeks, with morning and afternoon work (fee £3 3s.); neurology at the West End Hospital for Nervous Diseases for four weeks, daily at 5 p.m. (fee £2 2s.). Special courses to the end of the year are as follows: ophthalmology at the Royal Westminster Ophthalmic Hospital, November 9th to 28th, occupying every afternoon (fee £4 4s.); diseases of the chest, at the City of London Hospital, Victoria Park, from November 16th to 28th, morning and afternoon clinics (fee £2 2s.); venereal diseases at the London Lock Hospital, every afternoon and evening, November 16th to December 12th (fee £2 2s.); diseases of infants at the Infants Hospital, every afternoon, November 30th to December 12th (fee £3 3s.); proctology at St. Mark's Hospital, November 23rd to 28th, all day (fee £3 3s.); dermatology at the Blackfriars Skin Hospital, afternoons, November 30th to December 12th (fee £1 1s.). M.R.C.P. evening lectures are as follows: November 9th and 11th, Dr. Maurice Cassidy, "Prognosis in heart disease"; November 16th, Dr. Roodhouse Gloyne, "The clinical pathology of tuberculosis"; November 18th and 23rd, Dr. W. J. Adie, "Diseases of the nervous system." These lectures will be given at 8.30 p.m. at 11, Chandos Street, Cavendish Square. In connexion with this course Dr. Knyvett Gordon will give two lecture-demonstrations, "Anaemia" and "Leukaemia," at 10, Bedford Square, at 8.30 p.m., on November 25th and 27th. (Fee for each lecture, 10s. 6d., payable to the Fellowship in advance or at the lecture room.) A free lecture on "Gastric and duodenal ulcer" will be given by Lord Moynihan on November 11th, at 4 p.m., at 11, Chandos Street. Other lectures of this series will be given by Sir Henry Gauvain, Mr Tudor Edwards, and Mr. Cecil Joll. Copies of syllabuses of all courses, lectures, and demonstrations may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The next election to the Grocers' Company Research Scholarships, awarded with the object of encouraging original research in sanitary science, will take place in May, 1932. They are of the value of £300 each, with an allowance to meet the cost of apparatus and other expenses in connexion with the work. The award is for one year, but renewable for a second or third year. Forms of application and further information can be obtained from the clerk to the Grocers' Company, Grocers' Hall, London, E.C.2.

The sixth annual congress of French-speaking psychoanalysts is being held in Paris on October 30th and 31st. The papers include one by Dr. G. Parchemeney on the hysteria of conversion, and another by Mme Jouve-Reverchon on hysteria from the psychiatric standpoint.

The eighth Voyage Médical International on the Riviera, organized by the Société Médicale du Littoral Méditerranéen, will take place from December 26th to January 9th, under the presidency of Professor V. Balthazard, dovon of the Faculty of Medicine of Paris, and under the leadership of Professors Laignel-Lavastine and Emile Duhot. The principal places to be visited are Marseilles, Aix-en-Provence, Hyères, St. Raphael, Cannes, Juan-les Pins, Nice, Menton, Monaco, Monte Carlo, San Remo. Further information may be had from the Federation of the Health Resorts of France, Tavistock House (North), Tavistock Square, W.C.1.

The dedication stone of the new Freemasons' Hospital and Nursing Home at Ravenscourt Park, London, W., will be laid next year by the Duke of Connaught, Grand Master of English Freemasons. The new hospital, to replace the present building in Fulham Road, will have 180 beds. A medical consultative committee, with Sir D'Arcy Power as chairman, has been appointed to advise the trustees on matters relating to equipment.

The twenty-second annual exhibition of electrical, optical, and other physical apparatus is to be held by the Physical Society and the Optical Society on January 5th, 6th, and 7th, 1932, at the Imperial College of Science and Technology, South Kensington. As on previous occasions, there will be a trade section and a research and experimental section. The section for the work of apprentices and learners is to be continued.

A congress for the study of traumatism in the mining industry was held at Stalino (Ukraine) on October 21st, when the following subjects, among others, were discussed: (1) traumatism and national economy, (2) statistics of industrial accidents; (3) the human factor in traumatism, (4) the role of subterranean medical posts in the campaign against traumatism, (5) organization of medical help, (6) sanitary instruction.

Sir William Henry Goschen has been appointed chairman of the committee of the London Hospital in succession to the late Viscount Knutsford.

The League of Nations has accepted the proposal of the Brazilian Government to erect, at Rio de Janeiro, an international institution for the investigation of leprosy.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology, Westcent, London*.
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London*.
MEDICAL SECRETARY, *Mediscera Westcent, London*.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*, telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*, telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Cervical Adenomata

"CURTIS VERA" would be glad to know of any treatment for multiple soft adenomata with slight pigmentation at the base of the neck and shoulders. The condition is of long standing, and may have been caused by a former mild but chronic seborrhoea of the scalp.

Alopecia Areata

"AREA" writes: I have a case of alopecia areata in a girl of 14 about which I would like to have your opinion. It has existed for some years and was treated in 1928 at a department of the neighbouring general hospital. The lotion prescribed was the usual [illegible] and has done no good. The top of the head is [illegible] for a tuft like a Chinaman's queue. The [illegible] and in the front is quite thick.

Persistent Mild Pyrexia

Dr. Thos. McCulloch (Cambuslang) writes: I wonder if any reader can throw light on a question which is causing me a little anxiety—namely, Can the normal body temperature be higher than 98.6° F.? What prompts this query is the fact that I have under my care a little girl whose temperature has only on one or two occasions since July been lower than 98.6° F. The condition causing the pyrexia at that time was a mild attack of tonsillitis accompanied by slight enlargement of the tonsillar gland on one side. This cleared up in a few days, but the child's mother took the temperature regularly for several weeks afterwards, and found it to be raised on every occasion. The average daily readings are 98.6° in the morning and 98.8° to 99° in the evening. I have examined the child very carefully for lung conditions, etc., but am quite unable to discover any cause. She is aged 7, goes to school every day, and behaves and plays about like any healthy young animal. I shall be glad to know of anyone having met with a similar case.

Catarrh of Upper Respiratory Tract

Dr. B. M. Sayth (Srinagar, Kashmir) writes: In the *Journal* of June 13th "S. S." inquires about catarrh of the upper respiratory tract. I myself have been a sufferer from this complaint for many years, when compelled to live under certain climatic conditions, such as the dust of the Punjab or the smoke and fogs of large English cities. I have tried every sort of palliative remedy, and have found relief on two occasions only. One was when I had protein shock (intravenous T.A.B.). On this occasion the catarrh stopped immediately and completely for some weeks, and then returned gradually. I should have repeated the treatment but for the fact that my reaction was so severe as to be dangerous. The other thing that has relieved it has been exposure to radiant heat, and also the high-frequency "radio" current. On two occasions a severe attack has been completely stopped within two days with this treatment.

Income Tax

"G. P." has lodged his declaration of income, computing his assessable income for 1931-32 on the amount of his earnings for the year ended March 31st, 1931. Owing to ill-health he has recently had to employ an assistant for some months, and may have to continue doing so for some time. Can he claim any adjustment in view of the consequent drop in his net earnings?

*** No; unfortunately such circumstances do not justify a departure from the previous year's basis, though it could have been arranged otherwise if "G. P." had taken a partner instead of an assistant into the practice.

Housekeeper Allowance

"M. N." asks for further information with regard to this allowance.

*** The deduction (of £50) is given to a widower or widow whether there are children to be cared for or not, and to unmarried persons who have a female relative acting as housekeeper where the person making the claim has the care of a brother or sister. Hence it does not apply to the quite common case of a bachelor employing a housekeeper for his own comfort and not directly or indirectly for the care of a brother or sister.

LETTERS, NOTES, ETC.

The "Electrick" Piano Trick

Dr. A. B. Dunne (Doncaster) writes: Some few weeks ago I received a ticket for a lottery organized by the *Revista Internacional Medical*, addressed to me from Calle Mayor, 49, Villanueva y Geltrú, and bearing the Barcelona postmark. I am, I fear, a very careless fellow, and threw it into the wastepaper basket, and thought no more about it. However, that was not the end of the matter, for this week I received the gratifying and (certainly on my part) wholly unexpected news from the firm that the ticket which I had so lightheartedly thrown away, without even making a note of its number, had drawn the second prize—"an electrick piano." My joy at this windfall, however, was tempered by the fact that I have already in my house a pianola, a wireless set, and my daughter's gramophone, and as my house is not connected with the electric company's main I have no use for this valuable instrument, which will be shipped to London and forwarded free of cost to any address in England, etc. As I have no use for this instrument I shall be glad to let any hospital or other institution have it; but before they can become the fortunate possessors, there is one little matter to be attended to. It appears that, under the conditions governing the lottery, subscribers to the journal can alone receive a prize. I, unfortunately, have hitherto not been a subscriber, and so, prior to shipping the "electrick" piano to London, they ask me to forward a remittance of £2 10s. 3d. as soon as possible "in mandat or order de post or cheque, addressed to our director, Mr. Vicente Peris, Calle Mayor 49, Villanueva y Geltrú." Needless to say, I have not done so. This enterprise of the *Revista Internacional Medical*, I think, Mr. Editor, is well worth the consideration of your colleagues of the British medical press, and might be a further inducement to subscribe to their periodicals. Free insurance policies are poor stuff in comparison. Have any of your readers been lucky, along with me, in winning the "electrick" piano?

*** Several other medical men in the North of England inform us that they also have won the "electrick" piano, and in each case the number of the ticket that won the prize was 7890! We are glad to know that none of them has parted with £2 10s. 3d., and we hope that every prize winner has been equally incredulous.

The Post-Influenzal Cough

Dr. K. R. Dalal (health officer, Corporation of Rangoon) writes: Every practising physician will have read with great interest the very useful contribution made to our knowledge of this distressing trouble by Dr. G. Richardson in the *Journal* of April 18th. These persistent paroxysms of irritating cough, mostly coming on when lying down in bed at night, and whenever exposed to cold air or draught following an attack of influenza, once started are very hard to control, and bear a close resemblance to fits of whooping-cough. As stated by Dr. Richardson, most of us will agree that the treatment of this distressing sequel is most disappointing. However, I should like to bring to the notice of the medical profession one drug that I have found most useful in this condition in the few cases in which I have tried it. This is a synthetic drug called "acedicon," prepared by C. H. Boehringer Sohn of Hamburg in tablet form, containing 1/13 grain in each. For adults, half to one tablet may be given as required. I am indebted to Professor W. Griesbach of Hamburg University for bringing it to my knowledge during his tour of the Eastern countries last year.

Urobilinogen

Dr. Sheffield Neave (Huntly) writes: In reference to Dr. Chalmers's letter (October 24th, p. 780), I, too, have been making this test on various cases of illness, although being on a holiday, I have not access to my notes for particulars. I may say there is a point which lessens the importance of this finding—namely, that it is common to find the reaction disappear as the patient gets well. This is notably so in common constipation, which often gives a positive reaction.

Pseudo-Hermaphroditism

Messrs. J. B. Neal and R. Cox (King's College, London) write: In the interesting memorandum by Mr. G. S. Woodman on pseudo-hermaphroditism (October 24th, p. 750) we observe that there is no definite reference to secondary sexual characters, such as development of mammæ, hair, and hair, although the patient is referred to as [illegible]. The presence of female secondary characters seems improbable in the absence of ovaries, while the presence of a testis should predispose to masculine secondaries. We feel that it would be interesting to have further information about the type of secondary characters

Toxaemias of Pregnancy

Correction

The report of Professor F. J. Browne's address to the [illegible] Division on the toxaemias of pregnancy, published in last week's *Supplement*, contained an error which should be corrected without delay (page 235, bottom of column 2). Professor Browne did not recommend *hysterectomy* as a method of terminating pregnancy, which would be unjustifiable in any circumstances. He did recommend abdominal hysterotomy.

Vacancies

Notifications of offices vacant in universities, medical [illegible] and of vacant resident and other appointments at [illegible] will be found at pages 42, 43, 44, 45, 48, and 49 of the advertisement columns, and advertisements as to [illegible] ships, assistantships, and locumtenencies at pages [illegible]

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page [illegible]

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

Aortic Stenosis

385 I. A. CHRISTIAN (*Journ. Amer. Med. Assoc.*, July 18th, 1931, p. 158) states that there is a form of cardiac lesion, not infrequent, which is clinically so distinctive as to merit greater recognition than it usually receives. Its characteristics are: occurrence chiefly in males relatively late in life; slow progression with symptoms of decompensation appearing late, though not necessarily prolonged after their development; the presence of a systolic thrill and a harsh loud systolic thrill in the aortic area, with or without a diastolic murmur; often a characteristic pulse with a normal or decreased pulse pressure, enlargement of the heart, a history of rheumatism early in life, radiological demonstration of calcification in the region of the aortic valve; necropsy findings of stenosis of the aorta with calcified deposits in the cusps (the other valves not being organically abnormal); and great cardiac hypertrophy. The symptomatology is often curiously at variance with the pathological evidence of long duration, for these patients as a rule live a relatively short time after the symptoms develop. The physical signs are those of aortic stenosis with no aortic insufficiency or only a slight degree of it. The differential diagnosis between this condition and aortic arterio-sclerotic dilatation is difficult, but it is easily distinguished from syphilitic aortic insufficiency. Twenty-one such cases, with post-mortem confirmation, are reported.

Syphilitic Parotitis

386 C. CHARGIN and T. ROSENTHAL (*Arch. of Derm. and Syph.*, August 11th, 1931, p. 236), who record a personal case, and have collected 31 others from the literature in addition to those summarized by Gerber in 1913, state that syphilis of the parotid gland is a definite clinical entity; while not common, it is sufficiently frequent to warrant attention, especially since it may be mistaken for a tumour. It may occur early or late in the infection, and also in congenital syphilis. The early types run an acute course, and are bilateral as a rule, the later ones are usually more or less chronic and unilateral. The associated lymph glands are often swollen, when suppuration takes place, as it occasionally does, it is usually in these glands, and only exceptionally in the parotid itself. While the diagnosis of early syphilitic parotitis is easy, the parotitis of late syphilis may be difficult, since the condition has to be distinguished from a variety of tumours and granulomas.

The Pirquet Test

387 G. DE N. HOUGH, jun. (*New England Journ. of Med.*, August 27th, 1931, p. 437) gives the results of, and the conclusions drawn from, 1,000 consecutive von Pirquet tests carried out as a routine procedure on the same number of children suffering from orthopaedic diseases. The cases were classified in three groups: those clinically non-tuberculous, those clinically tuberculous, and those with proved tuberculosis. The combined results in the three groups showed that 817 were negative to both human and bovine tuberculin, while 101 were positive. In 63 only the test with the bovine preparation was positive, and in 19 only the human tuberculin was effective. In 29 positive cases, there was a marked difference in the intensity of the response; in 17 the bovine reaction was more intense, in 12 the human. In the clinically non-tuberculous, the human type caused a more intense reaction in 5, and the bovine in 2. In the clinically tuberculous patients the human type was more effective in 5, and the bovine in 12. In the proved tuberculous cases, the human type reaction was more marked in 2, and the bovine in 3. Hough emphasizes the importance of using both human and bovine tuberculin in von Pirquet reactions, since otherwise some cases will certainly be missed. If the assumption is justified that the skin reaction is specific for the type of organism, and that the cases showing variation are representative of the whole group, it can be inferred that in orthopaedic tuberculosis the bovine type of infection is approximately three times as common as the human.

Non-Venereal Prostatitis

388 W. T. BRIGGS (*Urol. and Cut. Rev.*, September 1931, p. 551) states that many do not realize that the prostate may be the seat of infection in patients who have never had a gonorrhoeal urethritis. He has found that almost anything that lowers the general or local resistance is of etiological moment, such as over-exertion, exposure to cold, drastic purgatives or constipation which disturb the bacterial balance in the intestinal tract, alcoholic excess, and acute infectious diseases such as small-pox, influenza, typhoid, and the exanthemata. Locally, trauma of any kind, whether instrumental, chemical or sexual, plays an important part. The organisms usually found in the smears or by culture are *B. coli*, diphtheroids, streptococci, staphylococci, and typhoid and paratyphoid bacilli. From a study of the literature and from his own experience Briggs concludes that 18 to 20 per cent. of all cases of prostatitis are of non-venereal origin. The diagnosis, however, often requires several examinations. The general symptoms consist of arthritis, neuralgia, myalgia, neurasthenia, and melancholia. The local symptoms vary, the most constant being urethral discharge, pollakiuria, and aching in the groins, testicles, or perineum. Erections are weak or absent, and there is premature ejaculation. Treatment consists in gentle prostatic massage and the passage of full-sized sounds, cold perineal douches, and intestinal hygiene.

Surgery

Treatment of Chronic Osteomyelitis

389 F. S. CHILD and E. F. ROBERTS (*New York State Journ. Med.*, August 1st, 1931, p. 937) give their experience of the Baer treatment with disinfected live maggots in nine cases of chronic osteomyelitis and one of tuberculous sinus. Baer introduced the treatment about three years ago, but the difficulty of producing disinfected maggots was only overcome in December, 1930. As a preliminary the diseased bone is freely opened with an osteotome, and all necrotic bone is excised. All sequestra having been removed, the wound is packed with sterile vaseline gauze, which is taken out 48 hours later, under gas anaesthesia. The maggots are hatched from fly eggs laid by the species *Phormia regina* and *Lucilia sericata*, the eggs are disinfected by washing in sterile distilled water, in sodium hypochlorite solution, and in 4 per cent. formaldehyde. The maggots are tested for sterility by inoculating duplicate sets of fermentation broth tubes for detecting aerobes, and deep meat tubes for anaerobes. Sterile maggots are gently scraped into the wound with a sterilized wooden spatula. They are enclosed by a cage cut out of 80-mesh brass screening cloth, which is held in place with strips of adhesive plaster, three are spaced to provide light, which draws the maggots deep into the wound, and to afford the air which is essential for their vitality. There is profuse discharge, which is permitted to drain through the screen. The maggots are left in the wound for five days, and are then washed out with normal saline solution, or removed with sterile forceps. After an interval of forty-eight hours there may be a further implantation. With the first application of

maggots the authors administer a prophylactic dose of tetanus antitoxin, since Baer reported tetanus in one of his early cases, with maggots which had not been disinfected. A mild sedative is at first necessary at night to allay the itching caused by the maggots. On the second, third, or fourth day the temperature rises to 102° or 103°, probably due to insufficient drainage; there is no purulent odour. Of the ten cases treated nine healed satisfactorily; one case of chronic osteomyelitis still requires further removal of necrotic bone. Eight to thirty implantations were required, the average being fifteen to eighteen. The time required to effect a cure has been eight weeks to six months. The authors consider this the most satisfactory method yet devised for the treatment of chronic osteomyelitis.

390 Prophylaxis of Post-Operative Pneumonia

A. I. Lourie and K. G. Podschibiakin (*La Gynécol.*, July, 1931, p. 391) report on the success of various steps they have taken to prevent post-operative pneumonia. Among general measures the use of purgatives and lavage of the digestive tract have been abolished. A large dose of sugar is given on the day of operation to raise the general body tone. Since the lungs take part in the general depression of physiological function caused by post-operative shock, an intramuscular injection of 1 c.cm. of ether with 1 c.cm. of camphorated oil is given at the end of all operations. The ether provokes an active hyperaemia of the lungs, facilitates expectoration, and by reinforcing alveolar peristalsis enhances the vital capacity of the lungs. In addition, carbon dioxide has been used to stimulate the respiratory centre, thus increasing the frequency and amplitude of the respirations. It was found possible and efficacious to prolong the effects of carbon dioxide administration by allowing the patient to breathe cold air during the recovery period. The body temperature was maintained by blankets and hot bottles, and the neck was well protected. When cold air from a large open window was inhaled by the patient, the respirations became forcible and remained so. Comparing the figures for the periods before and after prophylactic measures were in use, it was found that in 1925-6 among 186 laparotomies there were 27.4 per cent. pulmonary complications and 3.2 per cent. post-operative pneumonias. During the three years when injections of ether (1927), carbon dioxide (1928), and prolonged aspiration of cold air (1929) were used, among 214 laparotomies there were 18.4 per cent. post-operative pulmonary complications and 1.4 per cent. of pneumonia; in the year 1928-9 there was not one case of pneumonia.

391 Phrenicectomy

U. Bani (*Lotta contra la Tuberculosi*, June, 1931, p. 616) reports 368 cases of phrenicectomy for pulmonary tuberculosis performed by him between July 11th, 1924, and December 26th, 1930. In the majority of cases local anaesthesia only (1 per cent. novocain) was used. Of 242 patients, 214 were adults, of whom 143 were men and 71 women; 28 were children of both sexes. The youngest patient was aged 9 years and 4 months, and the oldest 53 years. The cases in adults were classified as follows: (1) 36 with an isolated pulmonary lesion with a single cavity; (2) 97 had fibro-caseous tuberculosis and little tendency to activity, of whom 51 had slight lesions in the opposite lung, while 46 were clinically unilateral; (3) 64 were ulcero-caseous forms with a tendency to activity, and almost all with lesions in the opposite lung. In 17 instances the operation was performed owing to the insistence of the medical practitioner or of the patient's friends in spite of the absence of indications; 165 cases had undergone artificial pneumothorax, which had subsequently been abandoned in 28. Artificial pneumothorax was continued after the phrenicectomy, and in 49 phrenicectomy was the primary operation. The best results were obtained in the first group; 18 patients who had been operated on more than two years previously were in an excellent state of health, and in the rest immediate improvement had ensued. The second group showed the next best results. Of 52 who had been operated on two years previously 19 showed a clinical cure, 21 considerable improvement, and 2[illegible] immediate improvement followed by a relapse. Of 8[illegible] patients in the third group who had been operated on two years previously, 11 showed considerable improvement, and 4 had obtained a clinical cure. No benefit was derived from the operation when no indications for it were present. Bani concludes that phrenicectomy is indicated in localized forms of pulmonary tuberculosis, forms with a tendency to fibrosis; and cases which show but little tendency to advance.

Therapeutics

392 Calcium Therapy

A. L. Lieberman (*Journ. Amer. Med. Assoc.*, July 4th, 1931, p. 15) records a study of the pharmacological effects of calcium lactate and gluconate. It was found that the effects of the first-named salt, though produced more quickly, lasted a shorter time, and the gluconate was chosen, therefore, as the most representative calcium salt. This compound can be given in repeated adequate doses without causing either irritation or necrosis. The most suitable adult dose appeared to be 3 to 4 grams, to avoid any irritation sequels, and to obtain more persistent results, this should be administered after meals. The blood calcium figure attains its maximum elevation within an hour after the subcutaneous or intramuscular administration of calcium, and within four hours after being given orally. Intravenous calcium therapy is dangerous because of the risk of sudden intravascular clotting and death. The urinary calcium figure is apparently a qualitative index of the blood calcium level. A urinary value of 10 to 20 mg. an hour appears to be most desirable in avoiding a hyper- or hypo-calcaemia. Highly suggestive digitalis-like effects (heart block, arrhythmias, and coupled beats) were noted; Lieb mann suggests that these necessitate further investigation.

393 Calcium Therapy in Dermatology

F. A. Diasio (*Med. Journ. and Record*, September 2nd, 1931, p. 237) considers that calcium gluconate has a definite value in the treatment of many of those dermatoses in which an actual or relative calcium deficiency is secondary to increased capillary permeability. Notes of cases of chronic urticaria are given in which the administration of calcium proved efficacious. The calcium salt of gluconic acid is tasteless, and fairly soluble; it is less irritating and toxic than other calcium salts, and has given very satisfactory results. The average dose of calcium gluconate is 60 grains every three hours during the day, its absorption being rapid if it is given between meals, and if it does not give rise to nausea. In acute conditions the oral administration may be supplemented by the intravenous injection of 10 to 20 c.cm. of a 10 per cent. solution as often as necessary; from 5 to 20 c.cm. may be given intramuscularly or subcutaneously to children, or to those who object to the acute local reaction following the introduction of this salt into the veins. Small doses are ineffective. Untoward results are said to be less frequent with the gluconate than with other calcium salts.

394 Scopolamine associated with Other Hypnotics

In the states of waking and sleeping two regions of the brain are particularly involved—the cortical, which is the seat of psychic activity, and the basilar, which contains the centres regulating sleep. In animals deprived of their cortex, certain hypnotics are inefficacious, while others retain their efficacy or are more active. Pick accordingly divides these drugs into two groups: cortical hypnotics such as chloral and chloralose, and basilar hypnotics. [illegible] include especially the barbituric derivatives. [illegible] Jeanne Lévy, and Mme P. Meyer-Oulié (*C. R. Soc. Biologie*, September 18th, 1931, p. 1522) record a series of experiments on the combination of scopolamine and chloralose, a cortical hypnotic, and with [illegible]

barbituric derivative and basilar hypnotic. Scopolamine was found to increase markedly the hypnotic effect of the former, but not that of the latter; on the contrary, it increased in intensity and duration the exciting effects of sonetyl. The authors consider that these results appear to justify Pick's distinction between cortical and basilar hypnotics.

Anaesthetics

395 Local Anaesthesia in Fracture Reduction

R. G. Carothers (*Journ. Amer. Med. Assoc.*, August 22nd, 1931, p. 517) emphasizes the distinction between fracture reduction procedures and such surgical operations as appendicectomy. In fracture cases no further trauma has to be caused; all that has to be done is a manipulation to restore the correct relationship of the injured parts, followed by the application of splints or plaster. If a 1 or 2 per cent. solution of procaine chloride is injected into the haematoma which is usually still present in recent fractures, pain is eliminated, muscle spasm disappears, and reduction is effected easily. Carothers remarks that in 270 cases he has seen no case of infection induced by this injection, which he has employed in all cases of fracture of the long bones; he has not tried it for fractures of the spine, head, pelvis, or ribs. After radiography the site of injection is selected and painted with iodine; with a fine needle a small wheal is made with procaine, and a larger needle with a fairly heavy shaft of the necessary length is then applied to the syringe. The needle is introduced through the wheal towards the fracture, and the operator feels round until he can easily withdraw blood into the syringe. He then injects 10 to 20 c.cm. of a 2 per cent. solution of procaine, the amount depending on the age of the patient and the size of the limb. If more than one fracture is present, each is anaesthetized similarly. After an interval of five minutes the patient is ready for manipulation. No preliminary preparations are required, and a skilled assistant is unnecessary. If the first attempt at reduction is seen radiographically to be unsatisfactory, the procedure can be repeated, for the procaine remains effective for about an hour and a half. In only two cases of the author's series was another form of anaesthesia necessary; one was an ankle fracture with complete dislocation of the astragalus upwards and backwards, and the other a case of fractured femur in which the needle probably entered a vein. Most of his patients received no pre-operative narcotic or sedative.

396 Limitations of Sodium Amytal Anaesthesia

Marie B. Kast (*Anesthesia and Analgesia*, July–August, 1931, p. 183), from an experience of 3,000 operations, concludes that the use of sodium amytal (sodium iso-amyl-ethyl-barbiturate) as a preliminary hypnotic, and as an aid to general anaesthesia, is very satisfactory, but should be limited to such use. When rapid sleep induction is desired, the intravenous method of administration is the best, but for more protracted induction satisfactory results are obtained by the oral, rectal, or intramuscular methods. In the first of these a dose of 3 grains of sodium amytal is given in a capsule at bedtime the previous night, followed in the morning an hour before the operation by a further one to three capsules, and by a hypodermic injection of morphine and atropine half an hour later. Amnesia is pronounced in a large proportion of patients. When employed in association with ether or chloroform inhalation there was a marked reduction in the amount of anaesthetic needed. Whether the effect is immediate by intravenous administration, or more delayed by the other methods, the recovery time is much the same, except when large doses have been given, or a cumulative effect has been produced by repeating the doses before the drug has been entirely eliminated. Larger doses are contraindicated in weak, asthenic, hypotension cases; in those cases of hypertension in which a too sudden drop in blood pressure might result in circulatory collapse; in diabetic cases not properly prepared with insulin; and in neck cases with marked infiltration and oedema of the tissues. Most satisfactory results were obtained in combination with nitrous oxide-oxygen anaesthesia for thyroid surgery and tonsillectomy.

397 Avertin

C. Coghlan (*Med. Journ. Australia*, June 20th, 1931, p. 737) advocates the use of avertin (tribromethylalcohol) in general surgery and obstetrics, and summarizes the British literature on the subject. The rectal administration of 0.1 gram per kilogram of body weight produces an anaesthesia sufficiently deep for minor operations; it can be supplemented by local or general anaesthesia for major work. Full anaesthesia can generally be obtained from 0.125 gram per kilogram, after a preliminary injection of morphine with the addition of 30 c.cm. of a 20 per cent. magnesium sulphate solution and 1 c.cm. of 3 per cent. narcophin. For obstetrical work 0.075 to 0.1 gram per kilogram is used, and repeated if necessary. Owing to the danger of decomposition into hydrobromic acid and dibromacetaldehyde (the latter being most irritating to mucous membranes and setting up inflammation) avertin must be tested before administration by the addition of two drops of a 1 in 1,000 solution of Congo red in distilled water, which in the presence of decomposition gives rise to a purple or blue colour. The rectal injection is made very slowly through a catheter inserted about 4 inches, with the patient lying on the side; in from three to five minutes a natural quiet sleep results, which is sufficiently deep to permit removal to the theatre for operation twenty to thirty minutes later. If the anaesthesia is very deep an airway should be established; should the depth of anaesthesia be insufficient, it can be deepened by the administration of a little ether. The drug has no deleterious action on the heart, kidneys, or liver, and produces only a moderate fall in blood pressure; the presence of amylene hydrate in the liquid preparation, as a respiratory stimulant, counteracts any slowing of the respiration.

Obstetrics and Gynaecology

398 Vaginal Cysts Obstructing Delivery

W. Spitzer (*Zentralbl. f. Gynäk.*, August 1st, 1931, p. 2348), who records an illustrative case, remarks that a cyst is one of the rarest tumours affecting the vagina; it is extremely uncommon for it to obstruct delivery. The only previous case of the kind was reported in 1912 by Fischer in a 3-para, aged 36, in whom a vaginal cyst weighing about 440 grams was removed during extraction by forceps; the subsequent delivery of the child was easy. Spitzer's patient was a primipara, aged 30, in whom the delivery of a child with a face presentation was delayed by a cyst in the right vaginal wall. The contents of the cyst were evacuated, and after injection of pituitary extract a living child was born. The cyst was subsequently removed without difficulty. Its localization and anatomical structure showed that it arose from Gärtner's duct.

399 Radiographical Diagnosis of Foetal Death

According to F. Szellő (*Arch. f. Gynäk.*, May 6th, 1931, p. 495) it is possible, with good technique, to decide by a radiographical examination whether the foetus is alive or dead in the uterus. Illustrative cases are recorded in which the *x*-ray diagnosis, whether of life or death, although conflicting with clinical findings was afterwards proved correct. The chief signs of foetal death are: (1) flattening of the cranial vault, most evident in the parietal region; (2) increased flexion of the vertical column; (3) Spalding's sign, which, though of great significance, becomes evident at a later stage than these; (4) diminution in the radius of curvature of the skull; (5) smallness of the long bones in comparison with the duration of pregnancy; and (6) dimness of the bony shadows as decalcification advances. The sign described

by Spalding in 1922 consists in an overriding of one cranial bone over another at the sutures, as of one tile over another in a roof. Szellö describes a case of foetal death in which this sign was detected as early as the fifth month. Spalding's sign, but in a less marked degree, may be given by the skull bones of the live foetus during compression due to labour pains; it is therefore only reliable before labour. Integrity of the amniotic sac is another essential.

400 Urinary Tract Infections during Pregnancy

H. L. Morris and L. J. Langlois (*Amer. Journ. Obstet. and Gynecol.*, August, 1931, p. 211) believe that the importance of urinary tract infections as a complication of pregnancy has not been sufficiently emphasized, and they record a study of 58 cases of such infections occurring during or after child-bearing. Of these patients 27 were primiparae and 31 multiparae; in 48 the complication was ante-partum, and in 10 post-partum. Infection, ureteral obstruction, hydronephrosis, and hydro-ureter occurred three times more often in the right kidney than in the left. *B. coli* was the usual cause of infection, and the predisposing factor was poor renal drainage associated with intestinal stasis. The onset of urinary symptoms, such as frequency of micturition and nocturia, usually occurred during the fourth month of pregnancy. Constipation was the most important gastro-intestinal symptom; among others were headache, vertigo, and blurring of the vision. Physiological variations in the vesical mucosa and contour began as early as the second month, and persisted until after delivery. Pyeloscopy was an important adjunct to pyelography. The authors remark that an early diagnosis is most important, since success in treatment depends on the early institution of appropriate measures. All foci of infection, including intestinal stasis, must be eradicated, and local and general treatment be given. Patients with renal ptosis were greatly benefited by wearing properly fitted abdominal supports.

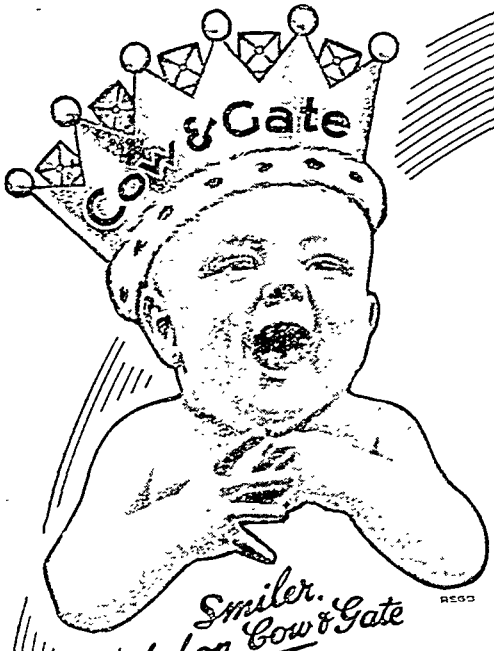
Pathology

401 The Pathology of the Placenta

A. N. Morosovax (*La Gynécol.*, August, 1931, p. 452) reviews the functions of the placenta from the morphological point of view as respiratory, alimentary, and excretory. The resistance of the organ is low, and it readily submits to a variety of histological modifications. It represents a barrier between the foetal organism and the maternal organism, but endogenous and exogenous toxins can escape its normal filtering function, chief among which is the syphilitic infection. Normal modifications of the histological structure of the placenta are seen in 48 per cent. of cases in healthy women. In syphilis histological alterations are manifest in 96 per cent. of cases, but are only definitely characteristic in 27 per cent. Such alterations as small areas of necrosis, deposits of calcareous salts, and sclerosis of the villi and vessels; leucocytic infiltrations of the chorion, and often also of the cord, are frequently present. The relationship between the weight of the foetus and the weight of the placenta was studied in syphilitic and non-syphilitic cases. The conclusion reached was that although the weight coefficient was raised three times more frequently in the syphilitic than in the non-syphilitic, yet as a diagnostic sign it did not possess an absolute value, since the placental weight could be influenced by other causes. In the tuberculous mother this structure was found to be altered in 60 per cent. of the cases, the modifications being the presence of many calcified nodules, proliferation of the syncytium, and the appearance of a grosser stroma of the villi. Morosovax adds that although much information may be obtained from the histological examination of the placenta yet the variations may be so wide within normal limits that no diagnosis can be based on these appearances alone without due consideration being given to all other evidence.

402 Squamous Epithelium in the Corporeal Endometrium

M. Boschetti (*Ann. Ostet. e Ginecol.*, June 30th, 1931, p. 631) quotes from the literature some twenty cases in which nodules of pavement epithelium were discovered in the endometrium, either in curettings or in the ablated uterus; the subsequent history showed that the findings did not justify a diagnosis of carcinoma. In Boschetti's case a woman, aged 35, was curetted for six months' meno-metrorrhagia; one large fragment contained, in a hyperplastic area of endometrium, nodules of epithelium resembling structurally and tinctorially the deeper layers of pavement epithelium, and connected with the basal cells of the cylindrical epithelium of the endometrial glands. In the uterus, removed two months later, neither corporeal nor cervical endometrium contained pavement epithelium. Boschetti concludes that in rare cases hyperplastic endometrium of the corpus uteri may contain benign nodules of epidermatization. It is possible that in some instances these nodules are the precursors of carcinoma, but their significance is not so serious as von Franqué has recently maintained. In rare cases gonorrhoea, tuberculosis, or pyometra gives rise to stratification of the corporeal endometrium.



403 Toxic Properties of Staphylococcal Filtrates

The toxicity of sterile filtrates of haemolytic streptococci for the cells of the body has been demonstrated by their destructive action on leucocytes (the leucocidins), on erythrocytes (the haemotoxins), on the skin (the dermatoxins or necrotoxins), and by their quickly lethal effect when injected into rabbits (acute killing poison). Opinions differ as to whether these various effects are due to one or several distinct substances. Julia T. P. Weld and Anne Gunther (*Journ. Exper. Med.*, September 1st, 1931, p. 315) relate a series of experiments to determine this point. These investigations indicated that the filtrates have several toxic properties, most important being the haemotoxic, the necrotoxic, the leucocidic, and the property of killing rapidly. The necrotoxic action appeared to be caused by a constituent in the filtrates different from either the haemotoxic or leucocidic one. Further experiments to determine if the leucocytes selectively adsorbed one or more toxins from atoxic filtrate were inconclusive. As a general rule filtrates which were strong in one toxic activity were found to be potent as regards the others. One "acute killing" unit was equivalent to 25 haemotoxic and to 80–100 necrotoxic units. In filtrates with less haemotoxic strength this quantitative relationship did not hold good, however, and there appeared to be no definite proportional incidence of the leucocidins and any other toxic properties. No precise conclusions as to the unity or plurality of toxins were deducible.

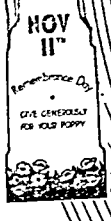
404 An Ultra-virus Test in Tuberculosis

F. van Deinse (*Ann. de l'Inst. Pasteur*, August, 1931, p. 135) describes a method by which the presence of a tuberculosis ultra-virus can be rapidly demonstrated. His experimental findings accord with those of Valtis, Nègre, Saenz, and other investigators, and the virus can be demonstrated in guinea-pigs two to four days after intraperitoneal inoculation with the filtrate from young cultures of tubercle bacilli. The development of acid-resistant bacilli originating from the ultra-virus is greatly aided by the presence of pus in the peritoneum; this can be produced by injecting precipitating calcium phosphate into the peritoneal cavity one to two days before the injection of the filtrate. The bacilli, which are found in great numbers in the pus, come neither from the animal organism nor from bacilli that have passed through the bougies. By this method, it is claimed, a differential diagnosis can be made between the ultra-virus and the bacillary forms of tuberculosis virus. The former form gives rise to the characteristic masses of acid-resistant bacilli in the first three days after inoculation, while bacilli appear about the eighth day; virulent bacilli are in the peritoneal pus only about the tenth day, and are never grouped in masses.

A Doctor writes.

28. 8. 31

Dear Sirs,—In reply to your letter of 20.8.31, I wish to let you know that my daughter Jean Margot, now aged 1 year 5 months, was a prematurely born child weighing 5½lbs. My wife's milk did not agree with the baby and she began to lose weight. Eventually I put her on Cow & Gate Full Cream until 9 months and continued with the half cream after that for a long period. The result is a bonny lassie whose photograph at 15 months I enclose for your use in whatever manner you wish.



I have just become the father of a son and heir and I do not hesitate to assure you that should it at any time become necessary to resort to artificial feeding it is going to be Cow & Gate every time for my child.

At the same time, as a result of the wonderful progress my daughter made with your preparation, I need hardly assure you that I lose no opportunity of recommending your product to any of my patients who consult me as to the non-progress of their babies who are on the breast.

Assuring you of my thanks and wishing emphatically to point out that this letter is entirely unsolicited by you but given of my own initiative in return for the debt I owe you for the progress my child has made, and I hope you will use this letter to your advantage.

Yours very truly,

L.R.C.P.I., L.R.C.S.I.

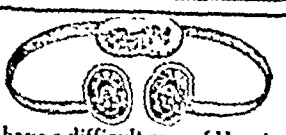
ABDOMINAL SUPPORT
MODEL N°1

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sound from varying ranges and angles.
5. It is entirely different, unopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.



"ARDENTE" STETHOSCOPE.
Dr. R. H. Dent makes Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS
Commended by all leading medical journals.—Mr. R. H. Dent will be happy to send full particulars and reprints on request, and also arrange demonstrations.

TREATMENT of EARLY MENTAL CONDITIONS

Medical Men having cases presenting any of those numerous states of ill health and disability now more generally recognised as often primarily due to minor psychoses and neuroses, and in need of investigation with view to decide on the treatment best likely to promote recovery and to prevent further mental deterioration, are invited to apply for particulars below, where for some years past a number of such cases, in both sexes, have been successfully dealt with.

The number in residence at any one time being strictly limited, close individual attention can be given, whilst the patient is provided with a comfortable home life in pleasant surroundings, with suitable occupation for leisure hours.

Certified cases and those definitely certifiable are not accepted.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFTDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Clifden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P. *Telephone*: Teignmouth 289.

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five gns. per week.

Apply, Dr D. E. M. DOUGLAS-MORRIS. *Telephone*: Newport, Pagnell 121.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

The MAUDSLEY HOSPITAL
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841–2

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.

IN-PATIENTS: (*a*) 189 beds (both sexes) in wards or separate rooms (*b*) 13 private rooms (for ladies) with special sitting room, garden, and dietary.

TERMS

(*a*) £5 a week, but in case of patients with legal settlement in the County of London *less sum may be charged according to means.*

(*b*) £6 6s. a week.

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Council *Mental Hospitals being attached to the Hospital.*

FEES, including all necessaries except clothing, from THREE to FIVE GUINEAS A WEEK.

Brochure and further information may be obtained from the MEDICAL SUPERINTENDENT.

Telephone: 157 Basingstoke.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to *from 15 guineas a week, beginning on October 19th, 1931.*

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings, all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, *nursing; medicines or vaccines, board and lodging.*

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 66

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel. Welbeck 8501

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) **M.C.CANTAB.** **M.S.LONDON.** **F.R.C.S.EDINBURGH.**

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our course.

¶ The Surgical Tutors of the College all hold either the *M.S.Lond.* or *F.R.C.S.England*, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

CITY HOSPITAL, *COTTINGHAM.*

RESIDENT MEDICAL OFFICER.

The Corporation invite applications for the appointment of a male Resident Medical Officer (single) to undertake, *under the Medical Superintendent*, the medical work of the Infectious Diseases Hospital. Commencing salary £350, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £450 per annum, *together with* board, laundry, and residence.

Applicants must be not more than 40 years of age, and must possess general clinical experience. The possession of experience in a fever Hospital will be regarded as an additional qualification.

The successful candidate will be required to reside at the City Hospital, and to devote the whole of his time to the service of the Corporation. He will be required to pass a medical examination, and to contribute to the Corporation's Superannuation Fund.

Applications, on forms to be obtained from the undersigned, with copies of not more than three *recent* testimonials, and endorsed "Resident Medical Officer, City Hospital," should be forwarded not later than noon on Saturday, November 14th.

Health Department, Guildhall, Hull. N. GEBBIE, Medical Officer of Health. October, 1931.

Borough of Ilford.

APPOINTMENT OF WOMAN ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from [illegible] Medical Women for the office of [illegible] Medical Officer of Health, for duties in connection with Maternity and Child Welfare, School Medical Inspection and General Health work. Candidates must possess Diploma of Public Health or similar qualification and have had post-graduate experience in Maternity work and Children's diseases.

The commencing salary of the officer will be £400 per annum, rising, on report of satisfactory service, by annual increments of £25 per annum to £550 per annum (or less if required with free board and residence at the Corporation's Isolation Hospital.

The person appointed will be required to devote whole time to the duties of the office, to reside at the Isolation Hospital, and to enter into a contract for the due performance and fulfilment of all the duties and conditions governing the appointment.

The appointment is subject to satisfactory medical examination, to the Staff Regulations, and to the *Local Government and Other Officers' Superannuation Act, 1922.*

Candidates must not be more than 45 years of age.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three testimonials (which will not be returned), and endorsed "Woman Assistant Medical Officer of *Health,*" *must be received* at my office at the Town Hall, Ilford, not later than Monday, November 12th.

Canvassing, directly or indirectly, is prohibited and will disqualify.

By Order,
ADAM PARTINGTON, Town Clerk.

Town Hall, Ilford.
October 26th, 1931.

Corporation of Kingston-upon-Hull AND THE HULL AND GOOLE PORT SANITARY AUTHORITY

SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Kingston-upon-Hull and the Hull and Goole Port Sanitary Authority invite applications for the appointment of a male *Senior* Assistant Medical Officer of Health at a salary of £800 per annum, rising, subject to satisfactory service, by annual increments of £25 to £1,000 per annum.

Applicants must be registered medical practitioners, *under* 40 years of age, and must possess a registered degree or diploma in Public Health or State Medicine.

The person appointed will be required to assist the Medical Officer of Health for the City in the administration of the Port Sanitary Service, Infectious Diseases Department, and to such extent for the central administration of the Public Assistance Hospitals, and must be prepared to do work in any other department of the Public Health Service, in accordance with the Corporation's scheme for the interchange of medical staff.

Experience in Port Sanitary Work and Infectious Diseases is essential.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the successful candidate passing a medical examination by a doctor approved by the Corporation.

Forms of application and further particulars of the duties and conditions of service may be obtained from the Medical Officer of Health, Guildhall, Hull.

Applications, endorsed "Senior Assistant Medical Officer of Health," together with copies of three recent testimonials, must reach the Medical Officer of Health not later than November 14th.

J. R. HOWARD EVANS, Town Clerk.

Guildhall, Hull.

The County Council of Middlesex.

ASSISTANT MEDICAL OFFICER.

The County Council invites applications for the post of Assistant Medical Officer in the Public Health and School Medical Department. Applicants must be duly qualified registered medical Practitioners, and should have had special experience of practical Midwifery and Ante-Natal work.

The duties of the post are the medical inspection of school children, the supervision of treatment of minor ailments, the carrying out of work under the maternity and child welfare scheme, and such other duties as may be required by the Council. The Officer appointed must devote whole time to the duties of the post, will act under the supervision and control of the County Medical Officer of Health, and must reside in such district as may be required by the County Council.

Salary at the rate of £600 per annum, rising after two years' service, by yearly increments of £30 to £750. Reasonable travelling expenses allowed.

The successful candidate will be required to contribute to the County Council's Superannuation Fund, and to pass such medical examination as the County Council may direct.

The appointment will be during the pleasure of the Council, and subject to one month's notice on either side.

Applications, stating (1) age, (2) qualifications and (3) previous experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than November 14th. No special application forms are provided. Envelopes must be endorsed "Assistant Medical Officer."

Canvassing, directly or indirectly, will be a disqualification.

ERNEST S. W. HART,
Clerk of the County Council.

Middlesex Guildhall, Westminster, S.W.1.
October 22nd, 1931

Hertfordshire County Council.

INSTITUTION FOR MENTAL DEFECTIVES, CELL BARNES.

APPOINTMENT OF MEDICAL SUPERINTENDENT

The Hertfordshire County Council invite applications from registered Medical Practitioners for the post of Resident Medical Superintendent of the Institution for Mental Defectives at present in the course of erection at Cell Barnes, near St. Albans. The commencing salary will be £800 per annum, rising by annual increments of £50 to £1,200, with unfurnished house, coal, light, and laundry. Such salary will, for the present, be subject to a temporary reduction of ten per cent.

The person appointed will be required to devote the whole of his time to the duties of the post and will not be allowed to engage in private practice.

The appointment will be subject to three months' notice on either side, and to the provisions of the Local Government and Other Officers Superannuation Act, 1922, for which purpose the successful candidate will be required to pass a medical examination.

Applications, stating age, which should not exceed 45, qualifications and experience in the institutional management of Mental Defectives, with copies of three recent testimonials, to be sent to the undersigned not later than Nov. 21st.

Clerk of the Peace Office, Hertford, Herts. October, 1931.

ELTON LONGMORE,
Clerk of the County Council.

County Borough of Huddersfield.

ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited from registered Medical Practitioners for the post of Assistant School Medical Officer.

The successful candidate will be required to devote the whole of his or her time to the duties of the office, and whilst these consist mainly of work in the School Medical Department they may also include work in any section of the Public Health Service. Experience in the diagnosis and treatment of Diseases in Children is essential.

The salary offered is according to scale, £500 increasing by £25 per annum to £700, and the commencing salary will be based on the candidate's previous experience in the School Medical Service. It will be subject to a temporary cut, which is in operation for one year, the salaries of all the corporation officials over £500 the cut will amount to £17 10s.

Applications, stating age, and giving full particulars regarding training, qualifications and appointments held since qualification, should be forwarded to the undersigned, along with copies of two recent testimonials, so as to reach him not later than Thursday, Nov. 12th.

JOHN M. GIBSON, B.A., M.D., D.P.H.,
Chief School Medical Officer.

City of Birmingham.

DUDLEY ROAD HOSPITAL.

SURGEON.

Applications are invited from fully qualified registered Medical Practitioners for the above whole time appointment, which will be limited to a period of twelve months.

The present Hospital accommodation is 926 beds, divided into General Medical, General Surgical, Gynaecological, Obstetrical, and Children's Disease sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electro-therapeutic Massage, Ultra-violet, and Electro-cardiographic Departments. Over 4,000 operations are performed annually.

Candidates for the appointment must have had good Surgical experience, and be Fellows of the Royal College of Surgeons (England).

The salary will be £750 per annum; furnished quarters, rations, laundry, and attendance, will be provided. Alternatively, a cash allowance will be paid if the officer appointed is non-resident. There may be shortly a general reduction of Corporation salaries, and the terms of this appointment will be subject to the same revision as may apply to existing officers holding similar appointments. The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

The appointment will be subject to one month's notice on either side.

Further particulars of the appointment may be obtained from the Medical Superintendent, Dr. F. W. ELLIS, at Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, and endorsed "Surgeon," should be addressed to Dr. ELLIS, and delivered at his office not later than Monday, November 9th.

F. H. C. WILTSHIRE, Town Clerk.

The Council House, Birmingham.
October 23rd, 1931

Erith Urban District Council.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

The Council of the Urban District of Erith invite applications from Medical Practitioners, under the age of 40 years and of not less than three years' standing in their profession, for the above appointment.

Inclusive salary £500 per annum, rising by annual increments of £25 to £700

[illegible] ject to the provisions [illegible] and Other Officers [illegible] and the successful candidate will be required to pass a Medical Examination. It is terminable by three months' written notice on either side, and is also subject to the Council's Standing Orders, Regulations, and Resolutions governing staff.

The appointment is a whole time one. The duties will mainly consist of work in the School Medical Department, but will also include duty in any section of the Health Services of the Council.

Experience in the certification of mental defectives and the possession of a registrable qualification in Public Health will be considered additional recommendations.

Applications, accompanied by copies of not more than three recent testimonials, must be made on forms obtainable from the Medical Officer of Health, Council Offices, "The Oaks," Belvedere, Kent, to whom they should be returned to reach him not later than November 3rd, endorsed "Assistant M.O.H."

Council Offices, "The Oaks," Belvedere. October 17th, 1931.

All communications to be addressed to the Branch Manager, BRITISH MEDICAL BUREAU, 33, CROSS ST., MANCHESTER.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

AMENORRHEA

Research of the past few years has shown that the two known hormones of the ovary, follicular and luteal, are supplementary in initiating the uterine progestational changes necessary for normal menstruation. The anterior pituitary, the "motor of the ovary," is of equal importance. For a potent effective combination of these indispensable elements prescribe

THE RELIEF OF BILIOUSNESS

Whether or not the term be a misnomer, there can be no doubt as to the reality and frequent occurrence of the syndrome colloquially referred to as "biliousness." The headache, the malaise, the coated tongue, the spots before the eyes and the giddiness may or may not be the consequence of toxic absorption or retention; or, alternatively, of reverse peristalsis carrying back to the stomach more than the usual amount of bile; but in any case, the symptoms nearly always disappear as soon as a normal downward intestinal current has been re-established.

For this purpose, long experience has taught that Eno's "Fruit Salt" is peculiarly efficacious. It is refreshing, and non-nauseating. If taken, as it should be, well diluted with water, it quickly empties and cleanses the stomach, passing through it even more rapidly than water itself. In addition to this action, it has been demonstrated that Eno has a useful choleretic effect.

The ENO "Medical Reminders."

The Proprietors of ENO'S "Fruit Salt" will appreciate the opportunity of sending, free of charge, to any member of the Medical Profession a copy of any of the following:—

"The Doctor's Pocket Remembrancer"
"The Practitioner's Pocket Book"
"The Panel Doctor's Pocket Book"
"The Doctor's Emergency Reminder"
"Urgent Abdominal Diagnostics"

J. C. Eno Ltd., 160, Piccadilly, London, W.1.

 [COPYRIGHT] [REGISTERED AS A NEWSPAPER

—THAT ENDS WELL

YOUR patient begins with a tablespoonful  continues with a teaspoonful  and finally stops it altogether  Surely, there is no clearer way to demonstrate  the therapeutic value of AGAROL  in the treatment of constipation.

Besides, Agarol Brand Compound is so easy to take. No oiliness, no artificial flavouring to get used to. It can be mixed with water, fruit juices, milk, with semi-solid food, used as a salad dressing in place of mayonnaise Serves you better—serves your patient better.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

A supply gladly sent for trial.

AGAROL *for Constipation*

INDEX OF TREATMENT

A Complete Guide to Treatment in a form convenient for reference.

Edited by **ROBERT HUTCHISON**, M.D., F.R.C.P.,

Physician to the London Hospital, and to the Hospital for Sick Children, Great Ormond Street, London

In conjunction with 90 Representative Authors.

FROM PRESS NOTICES OF FORMER EDITIONS:—

"We cannot do more than recommend it in terms of high laudation; it is a volume that should be in the hands of every practitioner of medicine"—*British Medical Journal.*

"Since we first reviewed this book on its appearance in 1908 seven further editions have been issued—a gratifying evidence of success which establishes it beyond the reach of criticism. Its general plan and high standard of excellence are doubtless well known to our readers"—*Lancet.*

"This index is well worthy of its success, reflecting as it does the latest teaching in medical science"—*Medical Press and Circular*

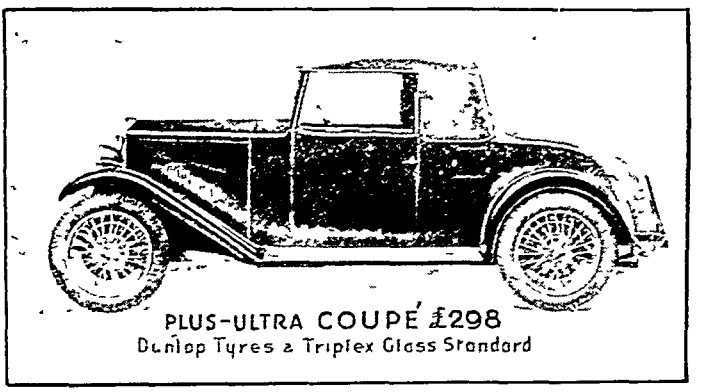
THE DOCTOR'S CAR

Here are a few of its features -



Commodious Two-Seater
(Bucket or single seats optional)

Large Dickey Seat

Large Yale-locked locker in rear of body with access from interior or exterior

Two Yale-locked cubby holes in dash

Drophead-opening front screen and easily operated winding TRIPLEX WINDOWS

PLUS-ULTRA COUPÉ £298
Dunlop Tyres & Triplex Glass Standard

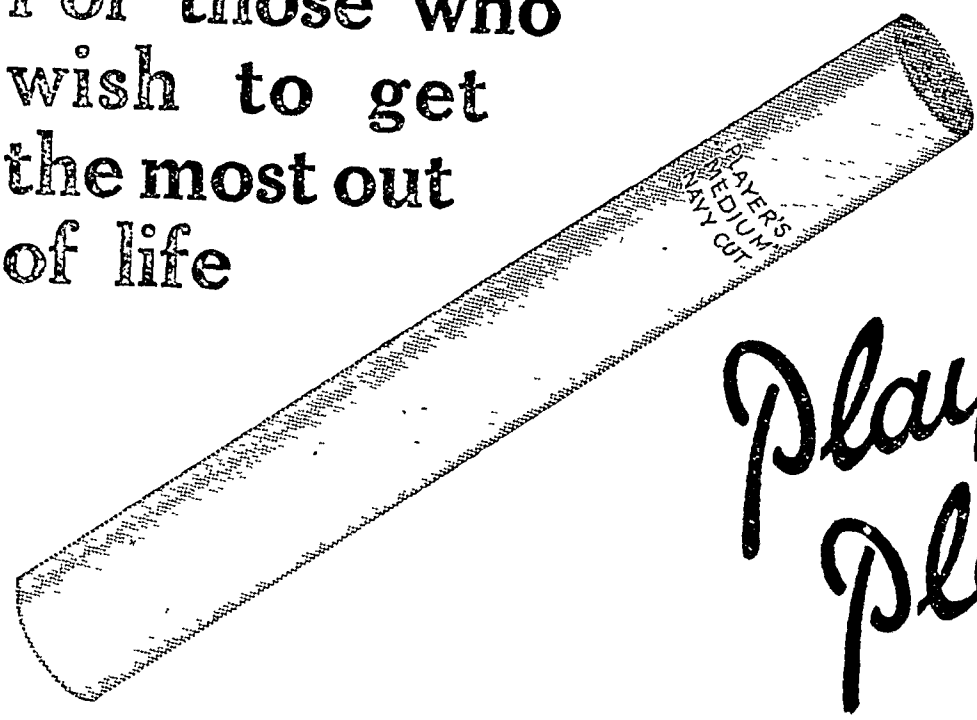
We acknowledge that that is a big claim, but we invite you to inspect the

Riley — As Old as the Industry, As Modern as the Hour

TWO-SEATER COUPÉ

to arrange a demonstration, and then confirm our claim or otherwise.

It is essentially a model designed and built for the professional man, and we are confident that with the Riley reputation supporting it—the reputation for long and economical service—you will agree we are justified in all we say about it.



Like all Rileys it has that turn of speed so infinitely useful in emergency—an exceptionally wide lock for traffic and garage work—The Riley Silent Third which ensures silence and easy change and that individualistic appearance so prized by the man of cultured tastes.

EDINBURGH—
6, Drumsheugh Gardens.

MANY readers of this announcement will be expecting delivery of their new cars during the next few weeks. The Motor Show has again proved an excellent stimulus to business in the Motor Trade. When delivered, your new car should receive expert attention at reasonable intervals in order to prevent undue wear and tear with consequent depreciation of value. The "M.E." Service exists for this purpose, and an expert staff of mechanics is provided at all the service stations, whose addresses are given in the left-hand column, where rapid and efficient attention to any job, large or small, may be secured. Incidentally, concerning the question of Insurance, it will pay you, as a medical man to consult first the Medical Insurance Agency, which has arranged the Doctors' Special Policy (underwritten at Lloyd's) giving comprehensive cover at exceptionally favourable rates

Those who have not already chosen their 1932 model should pay an early call at one or other of the spacious showrooms maintained by Messrs. Mann Egerton & Co., where every assistance is given by a staff made fully aware of the requirements of doctors as a result of this particular firm's long service to the Medical Profession. The "M.E." sales organisation enables extremely generous allowances to be offered in respect of used cars which it is desired to part-exchange for new models.

Insurance will naturally be arranged through the Medical Insurance Agency, thus completing a transaction which is sure to give every satisfaction. If, despite the temptations of the Motor Show, you have decided to retain your present car yet a little longer, it is worth remembering especially in these difficult times that certain economies can be effected, particularly in regard to Insurance, for, as mentioned above, the Medical Insurance Agency has arranged a special Policy for medical men, giving the fullest protection at low premiums.

. . . after the Show—remember!

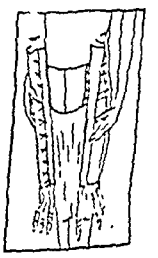
What has *Style* to do with Surgical Supports?



This: It makes *ONE* Garment Take the Place of *TWO.*

¶ The woman of to-day is wearing corsets. Corsets are absolutely essential to the present mode. This means that if a woman is obliged to wear a surgical support, the support *must* combine style essentials or she will be forced to buy a style garment in addition to her surgical one . . . ¶ Spencer Corsets diplomatically combine surgical features and style essentials. Thus they are the most economical garments a physician can prescribe. One Spencer takes the place of two garments.

Each Spencer Garment is designed individually for the one woman who is to wear it.

Spencer Supporting Corset, pictured at left, is a light-weight, flexible garment, with inner abdominal support. Adjustment of the inner support is made from the OUTSIDE—a convenience women patients appreciate. Special pads provided when prescribed.

Spencer Supporting Corset, sketch of back revealing adjustable abdominal support. Adjustment is made from outside the garment, for convenience.

RADIOLOGY SHOWS —quick return to normal tonicity

99 OUT OF 100 doctors recently interviewed recommend Brand's Essences of Beef or Chicken in cases of stomach atonicity, gastro-enteric catarrh and bowel trouble; in the post-influenzal state; and for the stomach atonicity in general convalescence. For over a century now, the medical profession of Great Britain has used these essences in this way.

X-ray photographs show why! Even in cases of very advanced stomach atonicity appropriate stimulation makes possible an amazingly quick return to normal tone; *and experiments with Brand's Essences show an equally rapid return to normal acidity accompanying this return of tone.* Brand's Essences of Beef or Chicken are made from the finest freshly-killed English meats—the pure juices solidified without preservatives of any kind.

X-ray photograph of a typically atonic stomach, with feeble gastric juice secretion

Photograph of the same stomach showing normal tone (and acidity) restored by correct stimulation

It is Wise to Add Wright's when prescribing "Liquor Carbonis Detergens"

Although there is no secrecy as to the composition of *Liquor Carbonis Detergens* (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required for the complete extraction of all the soluble antiseptic constituents is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD.,

On receipt of your professional card a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

OVER 900 BRANCHES IN GREAT BRITAIN

Modern diets often lack minerals

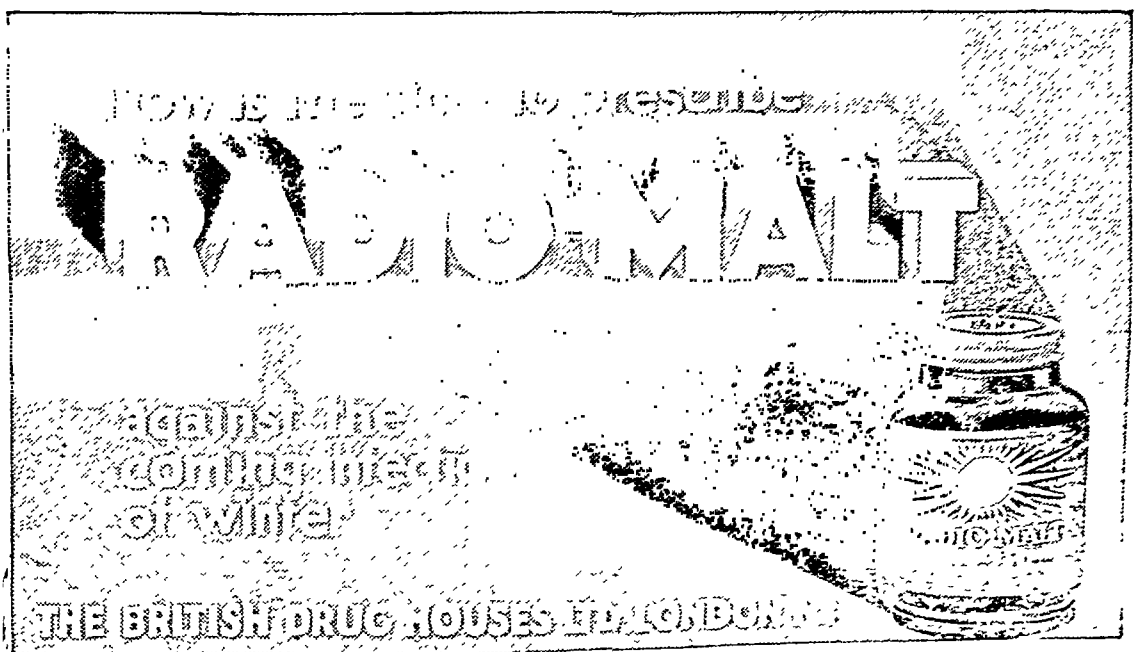
To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Compound Syrup of Hypophosphites "Fellows" contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.



Compound Syrup of Hypophosphites

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

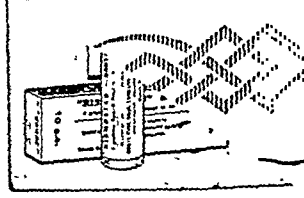
A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7.

M251

Works: KING'S LANGLEY, HERTFORDSHIRE.

ALOCOL

Colloidal Hydroxide of Aluminium



A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

Acute and Chronic Rheumatism

RESPOND SYMPTOMATICALLY.

Established Clinically in Active Practice for Over a Decade in U.S.A. and Canada, as Evidenced by Journal Publications:

Am. Jl. Med. Sci.,	1923, 165: 708
Jl. A. M. A.,	1921, 77: 1230
Jl. Lab. and Clin. Med.,	1923, 8: 217
Jl. Clin. Invest.,	1928, October
Lancet,	Sept. 29, 1928, p. 638

High dosage in acute fevers, or long courses in chronic cases, assure patients comfort without fear of harm to heart or kidneys. No serious side-effects have been observed in over a decade of use.

". . . . the introduction of Ephedrine into the clinic is an important contribution to symptomatic treatment . . . ."

(Lancet, 1931, 2, 141)

Experience in practice continues to demonstrate the many-sided uses to which Ephedrine can be applied:—for example, it is found to be *"especially valuable in relieving spasm of the bronchial muscle in such conditions as bronchial asthma, hay-fever, bronchitis and whooping-cough, in combating the fall of blood-pressure in spinal anaesthesia and in shrinking the congested nasal mucous membrane."*

To ensure the superior physiological activity associated with the naturally occurring laevo-rotatory substance, care must be taken in the choice of the Ephedrine employed (Abstr.: *B.M.J.*, 1930, 2, 18).

Ephedrine B.D.H. is the natural product manufactured in the B.D.H. laboratories from Ma Huang imported direct from China, and it can be relied upon to produce the maximum therapeutic effect without any attendant toxicity.

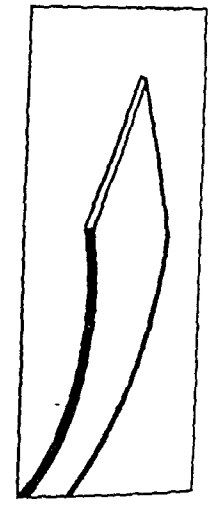
LONDON HOSPITAL CATGUT

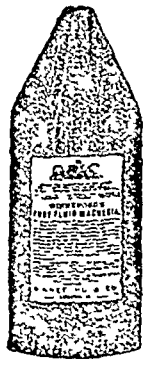


Curved Ophthalmic Advancement Suture

Exact size Eyeless Needle with London Hospital Catgut.

At the request of ophthalmic surgeons this needle has been specially designed for advancement suturing. Special features are that the needle point has a double cutting edge and makes a horizontal incision, through which the needle and ligature pass freely.

Supplied threaded with plain catgut, "Ultratan" catgut, silk, or horsehair as desired.



Needle magnified to show special point.

ALLEN & HANBURYS Ltd.

AND ALL THE LEADING SURGICAL EQUIPMENT HOUSES.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

PYRIDIUM

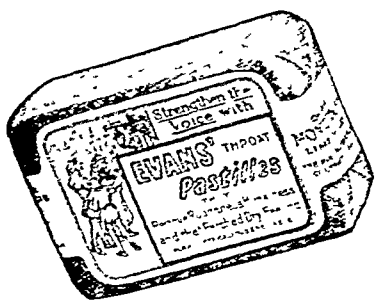
Pyridium is the registered trade mark of the Pyridium Corporation of New York to designate its preparation of phenyl azo alpha alpha diamino pyridine hydrochloride

MENLEY & JAMES LTD., 64, HATTON GARDEN, LONDON.

The chief characteristics and advantages of Pyridium include:

1 Powerful anti-bacterial action against several invading organisms, particularly those of the cocci type, also B. Coli com.

2 Freedom from toxic effects when taken in therapeutic dosage.



3 Ability to penetrate the tissues.

4 Marked power of stimulation to the proliferation of epithelial cells.

5 Early and gradual elimination through the genito-urinary tract.

6 Oral administration by means of coated tablets (each containing 0.1 gram of Pyridium).

Descriptive literature and samples of Pyridium gladly furnished to medical practitioners on request.

EVANS' THROAT *Pastilles*

MADE BY

EVANS SONS LESCHER & WEBB Ltd.

56, Hanover Street, LIVERPOOL
50, Bartholomew Close, LONDON

THROAT THERAPY

Evans' Pastilles are prepared to a formula of the Liverpool Throat Hospital. Their action is soothing and demulcent, the formula being carefully balanced with both these objects in view. Evans' Pastilles relieve harshness and irritation and maintain their effect for some time after the pastille has dissolved.

Sold in 1/- tins or in bulk for dispensing.

We will send with pleasure a physician's sample on request.

(*Æsculapius*).

Evans'

CONCENTRATED
DIPHTHERIA
ANTITOXIN

EVANS' Diphtheria Antitoxin is characterized by high concentration and exceptional freedom from inert protein matter. A low bulk dosage and the minimum of risk of disagreeable sequelae are thus ensured.

WHOOPING COUGH

Whooping Cough is a condition in which treatment with a suitable vaccine has proved remarkably successful. Some Practitioners, however, are deterred from using Vaccines, owing to fear of reactions, but this objection may be overcome by employing Detoxicated Whooping Cough Vaccine (Genatosan). In the preparation of this vaccine all the toxic elements of the germ are removed; as a result it is given to young children and infants without any harmful reaction and produces a high degree of immunity.

The following extract from a Practitioner's letter may prove of interest:—

"..... Some time ago, I resolved to try for the first time a vaccine in whooping cough and the results were so excellent, that I thought you would be interested to hear from me.

(*a*) Three children aged 3 years, 2 years and 8 months, were treated when the disease was about 10 days established; all were completely cured after the third injection—the mother described the effect to me as simply miraculous.

(*b*) Two aged 6 years and $3\frac{1}{4}$ years, who had relapses, were well after they had got the 2nd injection.

(*c*) An infant aged 8 months—the whoop disappeared after 1st injection. The cough was gone after 2nd injection, and the mother, who had tried everything and despaired of the child's life, was exceedingly grateful and assured me it was simply wonderful to see how the child had slept for the first time for days and was able to retain its food and rapidly put on weight. The Vaccine used was your Detoxicated Whooping Cough Vaccine. Speaking for myself, I can only describe the effects as magical, as the children were worn out and emaciated from coughing, vomiting, and loss of sleep."

Additional information regarding the above Vaccine will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

Once "A CONTINUAL ANXIETY— CONSTIPATED, CRYING & PRACTICALLY NO WEIGHT—"

January 21st, 1931

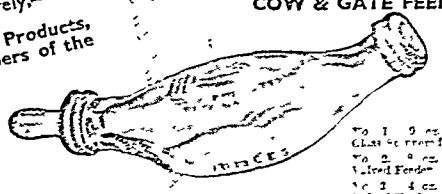
Dear Sir,

I enclose herewith a photograph of my son taken during the last few days.

He was born on April 17th, 1930, and weighed six pounds at birth. He is now 9 months old and weighs a little over 24 lbs., has six teeth and has the happiest disposition one could wish for.

He was breast fed during the first fortnight, and then put on——and——and raw cow's milk in turn. For the first month of his life he was a continual anxiety, constipated, crying and practically no weight. At one month he was put on Cow & Gate on the advice of my sister, a Health Visitor at Bicester, and from the first feed he improved. He slept the first night he had Cow & Gate from 7 p.m. till 7 a.m. with a feed at 11 p.m. which he took sleeping. From that date we hardly knew we had a baby, and it has been a delight to watch him grow. His teeth gave him very little trouble, and as you can see he has firm flesh, really fine bones, and no excess fat.

All this we thank your food for, and we feel that it is only fair to mention it. If his photo is of any use to you, please use it, but do not advertise his or my name, as my father is a Doctor and it might cause him embarrassment.



With many thanks for his health,

Yours very sincerely,——

¶ Clinical Samples of any of Cow & Gate's Products, will gladly be sent on request to members of the Medical and Nursing Professions.

BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN

Carbohydrates

Compared with maternal milk the carbohydrate content of cows' milk is considerably deficient, but in Lactogen—by suitable modification—this deficiency has been rectified.

Unlike ordinary dried milks, in which the carbohydrate is in the same proportion as in the raw milk, LACTOGEN CONTAINS PRACTICALLY THE SAME AMOUNT OF CARBOHYDRATE AS WOULD BE FURNISHED BY HUMAN MILK.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

Lactogen is prepared in England by Nestlé's—famous for more than fifty years for the purity of their milk products—from the pure, fresh milk of specially selected herds, grazing on picked English farms.

THE ANGLO-SAXONS MADE CHRISTIANITY A POWERFUL INCENTIVE TO PIONEER EFFORTS IN SOCIAL LIFE.—Bede relates: "On the Island of Thanet landed Augustine and his companions. The king (Æthelbert) came into the island and ordered Augustine and his companions to come and hold a conference with him . . . He gave them an abode in the city of Canterbury and they began to imitate the Apostolic manner of life in the primitive church . . . living in all respects conformably to what they taught." The Anglo-Saxon spirit was independent and logical, and it was the lives of the new-comers that appealed. Christianity was accepted as a religion to be translated into conduct. It is significant that Æthelbert was the first English king to frame a code of laws.

The illustration is from a manuscript written at Canterbury about A.D. 700.

Date: A.D. 597, Augustine landed.

DYSPEPSIA AFTER TEA

This is the portion of the leaf that is Ty-phoo.

To prove that "Ty-phoo" natural leaf-edge tea is valuable in various forms of indigestion we print below one of the testimonials which we are constantly receiving from medical men.

A Physician writes:

"I have found Ty-phoo tea most useful in treating dyspepsia, and many of my patients can take no other tea." "Time after time I have found on trying to leave it off I have had to go back to its use. It has been very marked to me the persistent pain I have suffered while taking Indian tea which has been absolutely removed on returning to 'Ty-phoo.'" S——, Esq., M.D. No. 0200.

(Over 12,500 Doctors are upon our books as direct buyers from us)

The Schorstein Memorial Lecture

ON

CHRONIC EPIDEMIC ENCEPHALITIS

WITH SPECIAL REFERENCE TO THE OCULAR ATTACKS*

BY

ARTHUR J. HALL, M.A., M.D., D.Sc. (HON.), F.R.C.P.

CONSULTING PHYSICIAN, SHEFFIELD ROYAL HOSPITAL; VISITING PHYSICIAN, SOUTH YORKSHIRE MENTAL HOSPITAL, AND RAMPTON STATE INSTITUTION FOR MENTAL DEFECTIVES

In the first place I desire to express my thanks for the honour of being invited to deliver this annual lecture, founded more than twenty years ago in memory of Gustav Isidore Schorstein. It was never my good fortune to meet him, but from what I know of the work he left behind, and from what I have heard from those who were his pupils or colleagues, I am sure that, had he been spared to complete his life's work, one more would have been added to that long list of world-famous names which is the proud possession of this great hospital and college.

The founders of this lectureship wished it to be a lectureship in clinical medicine. In choosing the subject of chronic epidemic encephalitis their wishes have, I think, been straitly complied with. Such knowledge of epidemic encephalitis as we have to-day is the outcome of clinical observation and clinical methods such as were practised and taught in Medicine when Schorstein first entered its portals.

Very soon after epidemic encephalitis first appeared it was found that in many cases the troubles did not end with the acute attack, but that as time went on fresh symptoms kept arising, different in character from, and bearing no direct ratio in severity to, those that had gone before. This is now recognized as a chronic stage of the disease. It follows the primary infection at varying intervals, and such infection may take place without causing any symptoms at the time. Thus in any outbreak of encephalitis, in addition to the *obvious*, the *anomalous*, and even the *abortive* cases, a certain number of people have a *silent* or *occult* infection, the first and only indication of which is the appearance of symptoms pathognomonic of the chronic stage. The features of this are by now familiar to all. I propose to consider some of them.

While the virus may attack any part of the nervous system, in its chronic stages it gives rise chiefly to three groups of symptoms: disorders of behaviour, disorders of mobility, and disorders of sleep. These are the "big three" of chronic encephalitis. Apart from them its effects are comparatively few and slight. I do not propose to speak of disorders of behaviour. They certainly involve the highest or psychic levels. Although they often complicate or even dominate the picture, they may be absent throughout. Disorders of mobility, on the other hand, are largely somatic, and represent dysfunctioning of upper middle levels, while disorders of sleep have both psychic and somatic components, and it is difficult to suppose that any levels altogether escape the consequences.

DISORDERS OF MOBILITY (PARKINSONISM)

The main features of this syndrome have been well known for more than a century as paralysis agitans. This, although not rare, was never common. Moreover, it is almost without exception limited to one period of life—namely, the period of decline.

With the advent of chronic encephalitis, large numbers of cases of the Parkinsonian syndrome have occurred in almost every country, affecting persons of every age, particularly young people. This increased field of observation of the syndrome at various periods of life has added greatly to our knowledge of the subject, and has shown that most of the differences between post-encephalitic Parkinsonism and paralysis agitans, which were at first thought to be diagnostic, are more apparent than real, and of little importance. Many can be explained by the difference in age of those affected.

Muscular Rigidity

The essential feature, common to all ages and to all causes, is the combination of a peculiar form of muscular rigidity with tremor. The rigidity causes slowness of action (as Walshe[1] rightly emphasizes), poverty of movement, and characteristic postures. It may progress to marked muscular weakness. It is entirely different from that found in lesions of the pyramidal system, and may properly be described as extrapyramidal. It is always present, sometimes to an extreme degree, but in paralysis agitans it has in the past been rather overshadowed by the tremor and the subsequent weakness. The very name *shaking palsy* has contributed towards this. The reason why more attention has been called to it in Parkinsonism is probably due to the ages of the persons affected. Stiffness and slowness are not very serious matters in persons in the declining years of life. They do not want to skip and jump. If they become a little less mobile it does not seem unnatural at their time of life, nor does it arouse much comment. But, when the same thing happens in youth or in early adult life, it is noticeable and it is resented. A young person wants to play games and to compete with his fellows, and from time to time the young Parkinsonian, hardly able to walk, suddenly runs or jumps apparently as well as ever he did. It is so surprising that it is called kinesia paradoxa.

This, however, is not a new phenomenon. It was seen occasionally in paralysis agitans when the elderly sufferer happened to be "younger than his years." Tilney described such a case in 1911 as "progression métadromique." Indeed, this capacity for making short vigorous spurts from time to time, in Parkinsonians, is as typical of the extrapyramidal syndrome as is the inability to keep it up for long. Unusual postures of extension, seen from time to time in Parkinsonism, have also been recorded in paralysis agitans. Thus Gowers[2] writes: "In very rare cases which must be regarded as paralysis agitans, the head is bent strongly backwards."

Tremor

Again, as regards tremor: it was thought in the early days of Parkinsonism that tremor was less common than it is in paralysis agitans. In many cases it is certainly less obvious, but there are exceptions. In some Parkinsonians it begins very early and is very severe. What, however, is not seen so often in the young Parkinsonian as in the older person with paralysis agitans is the markedly tremulous fingers. It is possible that this also may, to some extent, be attributed to the difference in ages. In the declining years of life tremulous fingers are not uncommon, apart from paralysis agitans. More than forty years ago Gowers remarked on the difficulty of distinguishing between the two. Perhaps the extrapyramidal syndrome helps to unmask this feature of declining years.

Gait

Age also plays its part in the matter of gait. Festination has been looked upon as the typical gait of paralysis agitans. Actually it only occurs when the disability affects the trunk and the legs to a certain considerable extent. If it does so more than that, walking is impossible; if less, there may be no festination.

* Delivered at the London Hospital, October 15th, 1931.

Macdonald Critchley[3] has called attention to the varieties of gait in his recent interesting paper on arterio-sclerotic Parkinsonism. In Parkinsonism, festination is by no means common. Even if there is a marked forward stoop so that the body is bent right over, provided that the legs are not seriously involved, the person walks bent over, but he does not festinate. Conversely, provided that the trunk is not pulled forwards, even when both legs are seriously affected, there is no festination, but a small shuffling step with no tendency to fall forwards. If the trouble is chiefly in one leg, there is no festination, however much the body is bent forwards; the sounder leg supports the trunk at every other step. Indeed, there is no single gait typical of this syndrome. Gaits of the most varied type may be seen, depending on the extent and severity of the parts involved. The most constant feature is the visible lack of swing in one or both arms. In fact, the more one sees of the extrapyramidal syndrome, the more do Parkinsonism and paralysis agitans approximate rather than diverge. They have, indeed, a topography in common. Such differences as exist are largely due to the different reactions and compensations of which nervous systems of different ages are capable.

Disorders of Sleep

Disorders of sleep were the distinctive feature of the acute disease. After the acute stage was over they continued to appear as the nocturnal insomnia of children. In both of these stages sleep was disordered as a whole. There was either too much or too little of it. In the chronic stage disorders of sleep, as a whole, are less common. They do occur; some Parkinsonians complain of lethargy, others of insomnia. A certain number suffer from narcoleptic attacks. Besides these there are other phenomena occurring in the chronic stage which may possibly belong to disorders of sleep. These are the peculiar periodic "attacks," usually involving the musculature of the eyes or jaws, the upper trunk and limbs, or the respiratory mechanism. The exact nature of these has given rise to much speculation. They are not seen in paralysis agitans, and do not occur in at least 75 per cent. of Parkinsonians. They are thus not an essential part of the extrapyramidal syndrome. Professor Bonhoeffor[4] of Bonn was, I believe, the first to put forward the view that many of these periodic attacks are connected with disorders of sleep. In 1928 he published a paper on dissociation of the components of sleep in post-encephalitis, in which he stated this view at some length. I had been led to a similar conclusion some time before I knew of Bonhoeffor's paper, and the grounds on which this conclusion was based I shall bring before you to-day. They not only support Bonhoeffor's theory, but to some extent clear away difficulties which presented themselves to him at the time his paper was written.

Oculogyric Attacks

The most common of these periodic attacks are the so-called oculogyric crises or ocular-fixation attacks, of which an excellent description was published by McCowan and Cook[5] in 1928. Out of 384 post-encephalitic Parkinsonians of whom I have personal records, 60 (about 15 per cent.) have these attacks, while in another 5 per cent. there are closely related ocular attacks, *differing slightly* in certain details. I shall refer to some of these later. The two sexes are equally affected. Most of them are young people. The onset may be sudden. The eyes are usually described as "suddenly shooting up into the head." In many cases, however, there is a definite warning, which may be longer or shorter, and may take various forms. As a rule, the eyes turn up. In some this is associated with slight lateral deviation, in others it is not. In a few, however, a downward movement may occur at the first, or may alternate with the upward movement. Much more rarely the movements may be entirely lateral, without any up or down element. The result is the same whatever the direction. The eyes become fixed there, and cannot be got back into their proper position. At the onset an attack can, at times, be made to pass off. Sometimes this can be done by the patient. Thus, during the onset the eyes can be brought down voluntarily for a few seconds, but they go up again. Sometimes they can be made to stay down. Strong suggestion may also cause an attack to pass off. One woman told me that, if she could catch her son when his eyes first began to turn up, she could prevent an attack developing. She added that, "If they once become fixed he goes to sleep in about five minutes." An attack may also be cut short by strong external stimuli of various kinds. Thus, in one case, forcibly pushing the head backwards ended an attack. Its repetition in other attacks was, however, without effect.

Their frequency and duration vary widely in different cases, and at different periods in the same case. They may occur at more or less regular intervals, or quite irregularly. There may be two or three per day, or perhaps only one every few weeks. In some cases they usually occur about the same time of day, in others not. They are much more common in the afternoon than early in the day. They may last only a few minutes or several hours, during which time the patient is helpless. In most cases the attack ends in sleep, and the patient wakes quite free from it. In a certain number of cases the attacks sometimes end in sleep, and at other times cease spontaneously. It is only in a few cases that they never end in sleep. Various circumstances will precipitate an attack, such as prolonged use of the eyes in reading, going to the "pictures," etc. Emotional excitement of any kind, or even suggestion, may be the starting point. Dr. Rees Thomas assures me that, among the mental Parkinsonians at Rampton State Institution, "having to do something they do not like" is sure to start an attack. Certain associated conditions may accompany the attack. The head may be retracted or turned down or to one side. There may be general restlessness and mental distress, or dizziness, with flushing of the face and diplopia. Existing tremor may be increased. There may be an associated opening of the mouth. In some cases there is a certain amount of pain in the head. As a rule pain is absent. All the cases which I have seen are definitely Parkinsonian, sometimes only slightly so. Indeed, in quite a number of cases the patients would be able to carry on their work if it were not for the attacks. So far, in none of my cases have the attacks ceased permanently.

Various explanations of them have been brought forward from time to time. It has been suggested that they are hysterical or hysteriform. Against this there is considerable evidence. Thus the descriptions of attacks are identical to the smallest detail in whatever country they occur; yet in all these places, though hysteria has been occurring for ages, this type of attack was unknown before epidemic encephalitis appeared. In the second place, the attacks do not, in my experience, arise by imitation. I have not seen a single case in which the attack could be attributed to being in contact with similar cases. Stern and others confirm this. Thirdly, although the attack may be cut short by suggestion, it is the common experience that suggestion has no permanent curative effect. Another very important reason, which will be discussed in detail later, is that in hysteria the movements are of a kind capable of being performed voluntarily by a normal person. The movement of the eyes which occurs in an oculogyric attack

ich a movement. It cannot be made by any voluntary fort.

Epilepsy, tetany, and cramp have also been brought orward as possible relations, but any such relationship in only be based on the supposition that the oculogyric stacks are active muscle spasms. Against such a view iere is a good deal of evidence that the position of the es during an attack, so far from being due to active asm, is the result of the eye muscles being in a state rest. This evidence is based on certain facts connected ith the normal act of closing the eyes. So long as the es are open the extrinsic muscles are in a certain state tone, which keeps them always adjusted for binocular sion, and prevents them from being moved in any rection beyond the point at which the pupils are just ear of the lids. The trigger is always at full cock.

When the lids are closed, as in sleep, this tone in the uscles is relaxed, the eyes are no longer adjusted for nocular vision, and they wander upwards behind the ls. We are unconscious of is, and have no control er it.

Its occurrence in sleep was st described by Sir Charles ell,[6] more than a century o, in the following words: When the eye is at rest in ep, or even when the eyelids e shut, the sensation on the tina being then neglected, e voluntary muscles resign eir office and the involuntary uscles draw the pupil under e upper lid. This is the ndition of the organ in rfect repose."

As has already been stated, most of the oculogyric ses, although the lids remain pen, the eyes behave in a milar way to that described Bell when the lids are osed as "the condition of ie organ in repose"—that they turn upwards. This the most common event the oculogyric attack, but in some cases they turn own; in others, to one side In 59 cases of which have records of the exact movements in the attacks the es turn up always in 44 (75 per cent), up and/or down 13 (22 per cent), to one side in 2 (3 per cent.). (For ie sake of simplicity no reference is here made to any companying lateral movement, such as "up and out" "forwards and divergent" The movements are ouped in the three horizontal planes only.)

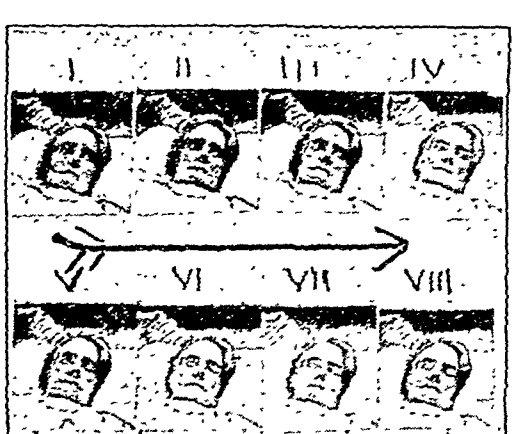

FIG. 1.—Closure of eyes in a case of right facial palsy. Serial pictures in the order of numbers. From I to IV the eyes are open. At some point between IV and V she has been told to close the eyes. At V the left eye has closed, the right eyeball has begun to move up very slightly. This movement continues upwards in VI and VII, and the eye then remains in the same position so long as the closure is kept up.

Position of the Eyes in Sleep

If Bell's statement that the eyes are turned up in sleep the whole truth, it is difficult to make the atypical tacks fit in with the conditions found in sleep.

It seemed desirable, therefore, to investigate more osely this question of the position of the eyes in sleep. uring the last two years, thanks to the generous help many resident officers at several large institutions ncluding a school for the blind) and others, 206 observaons have been made on the position of the eyes in deep ep. These have been made on persons of various ages id both sexes. Great care has been taken to be sure at they were fully asleep at the time of the observation. s in the oculogyric attacks the positions are grouped the three horizontal planes). In these 206 persons the eyes were found upwards in 54 per cent., forwards in 38 per cent, downwards in 5 per cent., and to one side in 3 per cent. In some the position was found to vary on different nights, in others it was constant. In one of those in whom the eyes were down the test was repeated on three nights with great care, and the position was the same each time. It is thus evident that Bell's observation is not the whole truth.*

In most cases the eyes are up in sleep, but in many they are not, and, what is most important for the matter in hand, they may be turned down or to one side, just as they are occasionally in the oculogyric attacks. Bonhoeffor realized this difficulty, that in the oculogyric attacks the eyes sometimes move in other directions than upwards. He tried to get over it by referring to certain cases published by Fleischer,[7] Kestenbaum,[8] and others, in which the eyes turned down in patients with injured upper lids, the so-called inverted Bell's phenomenon It is not possible to go into this in detail now, but it seems to me to bear a different interpretation

Eye Movements in Facial Palsy

As the position of the eyes in sleep did not prove so constant as was supposed, it seemed desirable to look more closely into the visible movement of the eye when the lid is closed or opened in cases of facial palsy It is well known that closure of the lids may take place in at least three circumstances It may be the momentary reflex blinking, the easy dropping of the lids at the onset of sleep, or the active closing at will. This third action may be carried further to resist opening, as when we screw up our eyes In order to follow more exactly the order of events when the attempt is made to close the eyes in facial palsy a series of moving pictures was taken of a case in which the right side was affected. (Fig 1) The patient was told when to close. (The pictures follow each other at about 1/16 second.) It is seen that when the patient is told to shut the eyes the movement begins by the lid closing, and the eye does not begin to change its position until the opposite lid is closed, or practically so, and it continues to move upwards for an appreciable time afterwards. The two movements are not synchronous, but consecutive.

There is every reason to suppose that the movement of the eye behind the lid on the sound side is identical in time and extent with that on the affected side

On the assumption that the sequence of events seen in this case of facial palsy is the normal procedure in closing the lids, it would seem that directly the lids cover the pupils the normal tone of the extrinsic eye muscles is inhibited, and that they go into a state of relaxation; not complete tonelessness, because, as will be seen later,

* Bell's statement seems to have been accepted without question by many writers on the subject. The only exception I can find is in Starling's *Principles of Physiology* (third edition p 565, where it is stated "There now appears to be irrefutable evidence that the eyes during sleep may occupy any position." But observations confirm this statement. [Ed.]—Professor Harris has since kindly informed me of a similar statement in Sir Victor Horsley's *Text Book of Physiology* (vol.), page , with reference to the observations by Karl Ludwig and Wittich, as far back as 1857.

they are ready to resume activity directly they are required. One might say that the trigger is now at half-cock.

Oculogyric Attacks and Sleep

With the muscles at rest the eyeballs assume also a position of rest. Why this should usually be upwards need not concern us here. We know from the observations on sleeping persons that in them it is so in more than half the cases, but we also know that during rest the eyeballs may be in any position. The account given above grouped them only in three planes, but, actually, the individual differences in sleep were extreme. In some they were very far up; in others they were up and out; in some they were forwards and converging; in others, down and to one side. Nor were they found to be necessarily in the same position on different nights. Possibly they change their position of rest during the same sleep. If, as Bell puts it, "the voluntary muscles resign their office" when the lids close, these individual variations are what we should expect. They correspond with the various positions assumed by the trunk and limbs in different individuals when asleep. Each finds his most restful position, and may change it during sleep. Also his position of rest may vary according to the particular parts that are most tired; this may be the same with the eye muscles.

B A C

Fig. 2.—Three photographs to illustrate (A) the presence of strong contraction of the occipito-frontalis in voluntarily looking upwards; (B) its absence when the eyes are still further up in a patient during an oculogyric attack; and (C) its absence in a case of bilateral facial palsy during attempted closure of the eyes.

If we put these facts together, there seems to be no essential difference between the position of the eyes in sleep and in the oculogyric attack. As regards position, then, if the latter is due to muscular spasm, the former may be also. If the eyes in sleep are resting, they may be resting also in the attack. The difference is not in the position of the eyeballs, but in the accompanying circumstances. In sleep all the remainder of the nervous system is resting; it is "whole sleep." In the oculogyric attack no other part is resting, not even the eyelids. This is unwelcome and disturbing, and gives rise to much of the accompanying distress. Looked at as a part of sleep the various features of these attacks easily fit into the picture. Thus, at the onset of an attack the eyes can momentarily be brought into normal position by voluntary effort, or by a strong stimulus from without. How reminiscent is this of the long dreary sermon, the drooping lids forced open for a moment only to close again, the partial awakening at sound of a parental cough, t sudden, complete wakefulness at those welcome wor "And now"!

One patient told me that, if in an attack he do go to sleep in about an hour, he gets a book and t read by repeatedly "pulling his eyes down," and th *if he can get interested enough the eyes will stop d* The interesting book often means late going to bed! T fact that in the majority of cases the attacks occur in t afternoon hours h also a strong flav of sleep. Most s ficant of all, not c does an attack us end in sleep, *sleep ends the att* In some it co within a few minute more often not f an hour or two o even several hou In a few cases on the attack never o in sleep.

Another fact w suggests that th upward position o the eyes in th attacks is not du

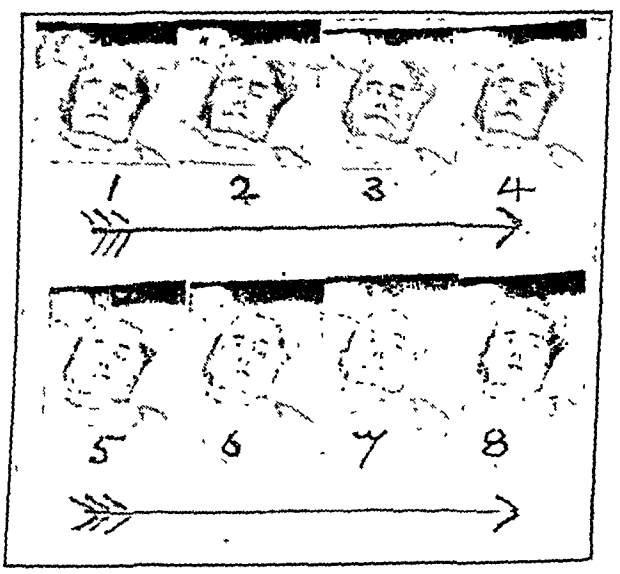

Fig. 3.—Opening the closed eye in a case of right facial palsy. Serial pictures in the order of numbers. From 1 to 4 the left eye is closed, the right eyeball far up and out. Between 4 and 5 she has been told to open the eyes. At 5 the left eyelid remains closed, but the right eye has moved slightly inwards and downwards. At 6 the left eye still remains closed, the right eyeball has got back into its normal position. At 7 the left eyelid has begun to open. Open further still at 8.

active spasm of the elevators is that there is associated contraction of the frontal muscle s occurs in normal persons on looking strongly upw This distinction is well seen in these photo (Fig. 2). The centre one, A, is that of a Par sonian youth who was trying to produce his oculogyric attacks in order to have his graph taken. He a the latter, but failed in former object. Th a real attack. His turned up only as f the normal muscle te allow them to go T are adjusted for the forehead is d wrinkled. In other there is the associated of the occipito frontal looking far upwards the other two, B and C eyeballs are higher they are in A, and, to the inhibition of tone, are under the the forehead shows wrinkles; B is gyric attack; C is a facial diplegia trying the eyes.

This absence of action of the occipito-f in oculogyric att been noted in all I have seen, and graphs of attacks as I have been able to out.* It is also supported by the fact that though the eyes are far up, the forehead is wrinkled.

* This statement applies only to the f In the early stages many irregular mov and facial muscles may occur in the attem

Attacks of Closed Lids

sides the oculogyric attacks, in which the eyes turn me direction, there are others in which the lids close cannot be opened These are not uncommon Some nts will tell you that there *seems* to be something nd the lids which is pulling, and which prevents them ing the eyes These are probably only a variation of other more common form The grounds for such a are to be seen in the serial pictures from the case acial palsy (Fig 3) When the woman is told to the closed eyes the first thing that happens is not the lid goes up, but that the eye begins to move n, and until it has reached its proper position the lid not show any sign of opening Just as in closure ie eyes, the two parts of the act are not synchronous consecutive, but now the order is reversed Until normal tone of the eye muscles has been resumed the tores palpebrarum cannot come into action In the k of "closed lids" the eyes go out of action when lids close, and, as in the oculogyric attack, they iot be brought into position again Until they are, eyes cannot open

ithin the walls of this college, many years ago, your t physician Hughlings Jackson no doubt often ated his famous aphorism "Nervous centres know ing of muscles, they only know of movements" complexity of the muscular actions in the movement losing and opening the eyes is an excellent example of great truth

Ocular Attacks due to Inhibition

here is, then, a good deal in favour of the view that e ocular attacks are not active muscular spasms, but er an inhibition of the muscular tone in the eye cles which normally follows closure of the lids Its is the covering of the pupils by the eyelids Con ely, the cue for the lids to open is the return of full in the eye muscles The oculogyric and the eye ure attacks are merely two slightly different modifica s of the same local inhibition In the former the rs hurry off the stage before the curtain falls in the r the curtain cannot be rung up because the actors not take up their proper positions on the stage rther case it is very disturbing to the management ing the attacks the head is often drawn in the same ction as the eyes, and may change with a change of r direction This is probably a compensatory action secondary to the ocular inhibition

ention was made earlier of other forms of periodic icks occurring in chronic encephalitis, particularly cting the jaws, upper trunk parts, and respiratory acts egards the two former, Bonhoeffer[4] suggests that the may be dissociated components of sleep The occa al attacks of yawning, in some cases leading to disloca of the jaw, and the so-called torsion spasms, which n bear a strong likeness to the stretching of the sleepy son, lend themselves to such a view

Prognosis in Parkinsonism

t would be difficult to paint a darker picture than is sented by chronic encephalitis as a whole If its acute ge chastised us with whips, truly its chronic stage stises with scorpions But it must be remembered t for various reasons it is usually the more severe s that are recorded in medical papers I should like mphasize the fact that there is also a rather less dark

There are at the present time a large number of kinsonians whose lives, at last seven years after in ion, are comparatively little interfered with by their ability Two years ago I followed up 525 of my cases Parkinsonism, and more than half were able to go about, look after themselves, and lead more or less ordinary lives It has not been possible to repeat that follow up this year, but I see many of these patients from time to time, and, although there are exceptions, I know that *most* of them are not any worse than they were two years ago Judged by their rate of movement in the arms as tested by the apparatus described in the *Lancet* in 1927, many of them show no increase of slowness, nor has any serious loss of power occurred

Among my cases of Parkinsonism in their seventh and even in some in their eleventh, year of infection, life is not incompatible with activities such as performing full household duties, playing in a football team, active gymnastics, going with boy scouts to camp and sharing fully in the duties, or working as a blacksmith all the week and holding classes for youths on Sundays One, a married woman, walks ten or fifteen miles every Saturday with her husband One youth dives and swims in the sea a great deal better than most people, another is a good rifle shot Some are managing businesses, one holds high military command *Quite a number of young Parkinsonian men and women have married since their disability* What the future has in store for any or all of these, and whether it is only a pause in a progressive disease or a real arrest of the process there are no precedents to guide us in forming an opinion Meanwhile, as the years go on, the latter seems more possible

For valuable help in preparing this lecture I desire to express thanks to Dr Vincent and his staff at the South Yorks Mental Hospital to Dr Rees Thomas and his staff at Rampton State Institution also to a large number of resident medical officers at the various Sheffield hospitals both voluntary and municipal and to the superintendent of the Blind School for their observations on the eyes in Sleep

ACUTE SPONTANEOUS HYPOGLYCAEMIA

BY

HENRY MOORE, M D, D Sc,

PROFESSOR OF EDICINE UNIVERSITY COLLEGE, DUBLIN, PHYSICIAN, MATER MISERICORDIAE HOSPITAL CONSULTING PHYSICIAN, NATIONAL MATERNITY HOSPITAL, DUBLIN

W R O'FARRELL, L R C P AND S I

HOUSE PHYSICIANS MATER MISERICORDIAE HOSPITAL DUBLIN

Cases of severe acute spontaneous hypoglycaemia have been so rarely reported in the literature that the recognition of the condition in practice is a reasonable excuse for recording the case reported below Moreover this case exhibited certain features different from those observed in any other so far described

elicited, and Babinski's sign was bilaterally positive. The skin was moist, there was blepharospasm, and the conjunctival reflex was diminished, but the pupils reacted normally to light. The urine, obtained by catheter, contained a trace of albumin, but no sugar, diacetic acid, or casts. Blood pressure was 90/70; no other abnormal findings were noted on clinical examination.

In discussing the diagnosis the possibility of acute hypoglycaemia was considered, but at the time no information could be obtained about her condition before admission. A fasting blood sugar estimation (Folin-Wu[1] technique) of 35 mg. per 100 c.cm.—the blood was drawn and the estimation made while the patient was unconscious—supported the diagnosis of acute hypoglycaemia; the blood urea, determined at the same time, was 60 mg. per 100 c.cm. A confirmation of this diagnosis was obtained by the intravenous injection of 10 grams of glucose in 20 c.cm. of distilled water; the injection took about four minutes, and before it was ended signs of returning consciousness appeared. Immediately after receiving the injection the patient became quite conscious and rational, she sat up in bed and asked where she was, the rigidity and blepharospasm disappeared, and the positive Babinski sign became bilaterally negative. We considered that the condition (now thought to be undoubtedly hypoglycaemic in origin) was probably not due to the administration of insulin, because it had become progressively worse in the first fourteen hours after admission.

Three hours after the glucose injection the blood sugar was 111 and the blood urea 30 mg. per 100 c.cm. By this time we learnt that the patient had never had diabetes and had never received insulin; she was therefore put on ward diet and glucose drinks. Glucose was not given after the second day in hospital, except once for a glucose tolerance test.

Previous History

The cause of the attack for which she was admitted to hospital in the first instance was undoubtedly acute spontaneous hypoglycaemia. The previous history, obtained a day or two after recovery from the acute attack, showed that her first three pregnancies had been normal, but the last baby, born in May, 1926, had been stillborn, and this delivery had been followed by a leucorrhoeal discharge which disappeared on treatment. Amenorrhoea had been present since the birth of the stillborn child. A year previous to her admission to the Mater Misericordiae Hospital she had complained of frequent attacks of dizziness, with "an inclination to faint," especially approaching meal-time. Because of these sensations she had gone to the out-patient department of another hospital, and had there received, on February 24th, March 3rd, and March 24th, 1930, three intravenous injections of novarsenobillon (0.3 to 0.45 gram), but the blood Wassermann reaction had been continuously negative. Three days before we first saw her (May 14th) she had actually become unconscious for a few minutes, and on the morning of the day before admission she was found hanging out of bed, with a dull, listless expression on her face, unable to recognize her husband and her friends. On the morning of the day of admission she was again found unconscious—with jerky movements of the limbs and frothy saliva round the mouth—and groaning, with an expression of pain on her face; she recovered partially, and was sent into hospital that evening.

Subsequent History

On the morning of May 16th the fasting blood sugar was 56 mg., and the blood urea 22 mg. per 100 c.cm.; the plasma nitroprusside test was negative, and there were no symptoms then, or afterwards, attributable to hypoglycaemia. At 4 o'clock on the afternoon of the same day, after a mixed ward breakfast at 9 a.m. and dinner at 2 p.m., the blood sugar was 122 mg. per 100 c.cm. On May 17th the fasting blood sugar was 66 without hypoglycaemic symptoms, and one hour after a breakfast, taken at 8.30 a.m., consisting of an egg, about 3½ oz. of bread-and-butter, tea without sugar, and 5 oz. of milk, it was 116 mg. per 100 c.cm.; but at noon, without further food since breakfast, it had fallen to 87. For several subsequent days, while on an ordinary ward diet, with cane sugar allowed in moderation, but no glucose drinks, the patient was kept under observation, and the following figures (mg. per 100 c.cm.) were obtained by blood analyses: sugar (fasting) varied from 72 to 76, calcium 9.75, inorganic phosphorus 1.5, cholesterol 271, uric acid 2.9, creatinine 2[illegible], non-protein nitrogen 37.5, and bilirubin less than 0.1. During this period no hypoglycaemic symptoms occurred. The blood sugar values obtained after the ingestion of 100 grams of glucose, 50 grams of starch, and 50 grams of levulose are shown in the following table.

Time in Minutes after Ingestion	Blood Sugar in mg. per 100 c.cm. after Oral Administration of—		
	85 grams Glucose	50 grams Levulose	50 (?) grams Starch
0	76 (nil)	74 (nil)	78
15	95 (nil)	—	95
30	125 (nil)	100 (nil)	94
45	132 (?)	—	78
60	130 (?)	75 (nil)	94
90	122 (trace)	72 (trace)	102
120	93	72 (trace)	125

The comments in parenthesis denote urinary sugar determinations on specimen obtained at the same time as the corresponding sample of blood.

A combined liver function and gall-bladder visualization test, after the intravenous injection of 2.5 grams of iodoxyl, showed that the dye was removed at the normal rate from the blood, and that the gall-bladder shadow was normal. A fractional test meal showed complete achlorhydria and no gastric mucus or bile. Routine gastro-intestinal and roentgenological examination by Dr. J. A. Geraghty [illegible] revealed some degree of ileal stasis, with a spastic caecum and possibly chronic appendicitis. The blood count showed 75 per cent. haemoglobin, 4,000,000 erythrocytes, and 10,000 leucocytes per c.mm., with a normal differential count. The blood pressure readings showed no subsequent significant change from the first figures. The blood Wassermann reaction was negative, and the patient's weight six days after admission was [illegible]. On the tenth day of observation the stools were examined and found to contain a large quantity of undigested starch, but there were only a few meat and vegetable fibres present and fat and fatty acid were absent; the diastatic power of the blood and urine was normal. Apart from one intravenous injection of glucose, followed by glucose by the mouth for the first day, no special treatment was given for the first fourteen days of observation, the patient being on an ordinary mixed diet. From the fifteenth day, drachm doses of dilute hydrochloric acid (*B.P.*) and 2 grains of pepsin were given in a mixture, three times daily after food during the remainder of period of hospital observation and for three weeks after discharge. As the faeces constantly contained a large [illegible] of undigested starch from the tenth day after admission, the first examination of the stools was made, it would seem that faulty digestion and absorption of starch might account for the constantly low level of the fasting blood sugar (62 to 76 mg. per 100 c.cm.), and that possibly these conditions might also have had some relationship to the hypoglycaemic attack on admission, when the blood sugar was only 35 mg. per 100 c.cm. The patient was therefore given 7½ grains of taka-diastase (Parke, Davis and Co.) three times in divided doses before, with, and after meals [illegible] thirty-second day after admission, starch [illegible] continuously present in large quantity in the stools, [illegible] the starch gradually disappeared, and on the [illegible] the taka-diastase was started no starch was found in the [illegible] stools; indeed, none was again found in the [illegible] subsequent examinations. The blood sugar [illegible] forty-eighth day was still only 74 mg. per 100 c.cm., [illegible] chloric acid was still absent in all specimens of [illegible] test meal on the forty-third day after admission. [illegible] decided to leave hospital on the forty-eighth day (June 1930) after admission, as she constantly refused [illegible] various tests during the last few weeks of her [illegible] promised to keep taking hydrochloric acid [illegible] as prescribed. She remained at home [illegible] three weeks, taking hydrochloric acid [illegible] directed, and she experienced no further [illegible] of hypoglycaemia. At the end of that [illegible]

the hospital for a day for observation, the stools tained no starch, but achlorhydria was still present, and fasting blood sugar was 75 mg. per c.cm. Refusing to ain longer in hospital, she again returned home, and ceased ake the hydrochloric acid and taka-diastase on July 25th, on August 8th we obtained a specimen of stools from her examination, which contained no starch. Another speci- (August 25th) again contained no starch, and no further ptoms suggestive of hypoglycaemia had been experienced. August 27th the test meal showed the presence of hydro- ric acid in moderate amounts in all but two specimens, this result was verified by another test meal next day. September 5th the fasting blood sugar was 78 mg. per c.cm., and 89 mg. three hours after a mixed breakfast. ut a month later a nurse called to see the patient, and id her apparently quite well; the patient stated that she experienced no inclination to faint, and had had no her convulsive attacks.

Literature

he clinical literature on the symptoms caused by te spontaneous hypoglycaemia is interesting, and con- d to comparatively recent years. Harris[2] in 1924 was arently the first to suggest that hyperfunction of the ts of Langerhans might, by causing hypoglycaemia, pro- e symptoms similar to those caused by an overdose of ulin. He reported five cases with comparatively mild ptoms which he considered to be thus explained, and mentioned the term "hyperinsulinism" in connexion ewith. A review of the literature would suggest that, le spontaneous over-production of insulin does explain ny of the recorded cases, certain of them may not ccounted for in this way; hence the descriptive noso- cal term "spontaneous hypoglycaemia" would seem e appropriate than "hyperinsulinism," the latter being rved for symptoms caused by true over-production insulin by the islets of Langerhans. Shih-Hoa and ao[3] in 1925 recorded moderate hypoglycaemic sym- ms from excessive purgation in a condition of partial vation. Wilder, Allen, Power, and Robertson[4] in 7 studied a case of carcinoma of the islets of Langer- s with severe hypoglycaemic symptoms; extracts of tumour tissue yielded insulin. Sendrail and Planques[5] 1927 stated that hypoglycaemia had been observed them in starvation, progressive muscular atrophy, and the pernicious vomiting of pregnancy. Finney and ney[6] in 1928 recorded a case of spontaneous hypo- caemia, and removed part of the pancreas, which was tomically normal. Schroeder[7] in 1928 produced hypo- caemia with symptoms in a woman by lowering the ohydrate intake. Thalhimer and Murphy[8] in 1928 cribed a case of spontaneous hypoglycaemia due to cinoma of the islets of Langerhans, and Allen[9] in 1929 cribed three cases, one of which was due to carcinoma the islets; in another, part of a normal pancreas was oved, with some improvement. Griffith[10] attributed ne cases of convulsions in infancy to spontaneous hypo- caemia. Howland, Campbell, Maltby, and Robinson[11] 1929 described a case of spontaneous hypoglycaemia, to a localized carcinoma of the islets of Langerhans, which removal of the tumour resulted in spontaneous e; this is apparently the only recorded case in which gical treatment was successful. In 1929 McClenahan Norris[12] described a fatal case due to adenoma of the ts of Langerhans. Allen, Boeck, and Judd[13] in 1930 iewed the surgical treatment of acute spontaneous oglycaemic attacks, and stated that three of five ients with pancreatic tumours, on whom partial createctomy had been performed, showed slight im- vement at first, but tended to relapse, and two ained no relief of their symptoms after this operation. mon and Tenery[14] in 1931 reviewed the literature and orded a further case of spontaneous hypoglycaemia with attacks of unconsciousness, due apparently to hyper-insulinism. Cushing,[15] Carr, Parker, Grove, Fisher, and Larimore,[16] and Womack, Gnagi, and Graham[17] record three cases of hyperinsulinism due to adenoma of the islets of Langerhans, with successful removal of the neoplasm and disappearance of the hypoglycaemic symptoms in each case. As far as we have been able to study the literature, about twenty-four cases of acute spontaneous hypoglycaemia with severe symptoms and apparently due to hyperinsulinism have been recorded. Several other references can be found to cases of spontaneous hypoglycaemia, acute and chronic, in some of which the symptoms tend to be less severe or absent, and in which the etiology may not always be clear. For example, the attacks have been attributed to liver insufficiency (possibly in relation to disorders of carbohydrate storage), non-pancreatic endocrine insufficiency or dysfunction, muscular dystrophy, renal glycosuria, lactation, and other causes. Wagner and Parnas[18] refer to a severe and acute case thought to be hepatic in origin, and Cross and Blackford[19] described a case of toxic hepatitis following the administration of neoarsphenamine intravenously, with symptoms definitely due to spontaneous hypoglycaemia. Mann[20] has shown that marked hypoglycaemia occurs in dogs after removal of the liver. Cammidge[21] mentions four cases of convulsive attacks due to chronic hypoglycaemia and associated with abnormalities of digestion, but he gives few details.

The symptoms of hypoglycaemia due to hyperinsulinism resemble those due to an overdose of insulin given hypodermically; the attacks may appear at intervals, and recovery may occur spontaneously, or after the ingestion of carbohydrate or injection of glucose, except in severe terminal attacks. The symptoms vary, according to the severity of the attack, from a sense of uneasiness, faintness, or apprehension, with perhaps sweating or great hunger, to vertigo, staggering, mental confusion, and coma, with or without convulsions, which, when present, are usually of the clonic type. Foaming at the mouth may occur, but loss of sphincter control is said to be uncommon.

Discussion

The case of acute spontaneous hypoglycaemia which we now record is, as far as we have seen in the literature, the first to be reported in detail in these islands, and, furthermore, faulty amylaceous digestion does not appear to have been heretofore described in any other case. The presence of a bilateral Babinski sign during the unconscious state, and its disappearance when consciousness returned after the glucose injection, is noteworthy. The cause of the hypoglycaemia in our case is not clear. The persistently low level of the fasting blood sugar, even when the stools contained no starch, would suggest, in the absence of indications to the contrary, hyperinsulinism. The severer degree of hypoglycaemia which was associated with and, as we believe, responsible for the unconscious state, never recurred during the period of observation. It is interesting to speculate as to whether the faulty digestion of starch, or a sudden exacerbation of this condition, when superadded upon the chronic hypoglycaemia, had an etiological relationship to the production of such a low level of blood sugar (35 mg. per 100 c.cm.) as to cause hypoglycaemic unconsciousness, but this question cannot be definitely answered from the information in our possession; we are inclined to the view, however, that possibly some such relationship was operative. This explanation would not account for the usual low level of fasting blood sugar in this case (62 to 76 mg.), for this level still persisted when the stools were free of starch, but without the occurrence of hypoglycaemic

symptoms. As judged by the tests performed, the liver function was normal; however, the possibility of mild liver injury, due to the novarsenobillon injections, might be considered, but does not seem probable. The blood urea figure was somewhat high while the patient was in coma (60 mg. per 100 c.cm.), but it was normal three hours after recovery. The absorption of glucose from the gastro-intestinal tract was normal, as judged by the glucose tolerance test. A puzzling feature is that the blood sugar curve, obtained after the ingestion of a mixed meal containing 50 grams of starch but no sugar, at a time when the stool was loaded with starch, did not show any great departure from what one might expect to be normal; apparently, although much starch passed through in the stool, a certain quantity was digested and absorbed. It is regrettable that further study of the starch digestion was not possible. We have no knowledge of the duration of the faulty amylaceous digestion previous to admission, and we find it difficult to appraise the significance, if any, of the transient achlorhydria. We regret that we were not able to study the case more fully, and our failure in this respect was due partly to the fact that we were not prepared to meet with a condition so unfamiliar to us, and partly to the poor co-operation of the patient, who objected to the tests and to being retained so long in hospital. We desire to record the case because it is possible that acute spontaneous hypoglycaemia may be a commoner condition than is suspected. On the other hand, although more than fourteen months have elapsed since we first saw the case, we have not seen another, even though we have been on the watch for one.

The patient was prevailed upon to return to the hospital for one day in July, 1931—that is, more than a year after her first admission. She looked well, and stated that she had had no attack of unconsciousness since we had last seen her (September, 1930), but that she had occasionally felt a little giddy, especially after eating "sweets" (meaning sugar and chocolates). Her fasting blood sugar was 62 mg. per 100 c.cm.; after the ingestion of 100 grams of soluble starch in water the blood sugar was determined every half-hour for three hours, and the figures were as follows (mg. per 100 c.cm.): 1/2 hour, 50; 1 hour, 62; 1½ hours, 67; 2 hours, 82; and 3 hours, 75. The stool contained no starch, meat fibre, or fat, but a few vegetable fibres were present. These findings tend to support the suggestion that hyperinsulinism was the cause of the chronic hypoglycaemia, and that the temporary superadded deficiency of the digestion and absorption of starch was a factor in helping to produce the acute hypoglycaemia responsible for the attack of unconsciousness which necessitated the first admission to hospital.

Summary

A case of acute spontaneous hypoglycaemia with severe symptoms is described; there was also chronic hypoglycaemia, and there was associated transient achlorhydria and faulty amylaceous digestion. The severe acute symptoms were promptly relieved by the intravenous injection of 10 grams of glucose.

THE TRANSPLANTATION OF BONE*

BY

W. E. GALLIE, M.D., F.R.C.S.

PROFESSOR OF SURGERY, UNIVERSITY OF TORONTO

The value of bone transplantation in the treatment of fractures is now so well established that it no longer needs argument to support it. As with so many other good operations, however, the development of a perfect technique has been slow, and failures have been frequent enough to prevent the operation from becoming as popular as it deserves. This paper is based on a review of the failures with which I have come in contact, and on a consideration of the errors that most often lead to bad results.

Causes of Failure

The chief cause of failure is infection of the wound. In almost every case in which it occurs the graft becomes a sequestrum and the fracture fails to unite. In the operation, therefore, asepsis is imperative. It can be acquired only by painstaking care, constant practice, and by the team work of surgeon and assistants, but the improvement in the results makes the effort well worth while.

There are still a few who fancy that when a piece of bone is transplanted from one place in the body to another it will continue to live, as does a transplant of free skin. This is an idea which must be eradicated if we are to reduce the percentage of failures. It hardly needs repetition that when a piece of bone is cut free from its circulation it dies, and must undergo complete absorption. The cells in the lacunae become necrotic at once and within two weeks have disappeared. Only those cells live which are free on the surfaces and in the open mouths of the Haversian canals, and so are capable of utilizing a supply of lymph, if such is available. These are the cells, however, which make the bone graft important in the treatment of non-union, and which must be humoured to the utmost if success is to be attained. Any abuse of them, such as boiling, immersion in antiseptics, and burning with a hot saw, must be guarded against, and any treatment of the graft that mechanically removes the periosteal and endosteal surfaces and leaves only hard compact bone, such as results from forcing a graft through a dowelling machine, must be avoided. I do not suggest that an autogenous dowel is not better than a boiled bone peg or a nail, but it certainly is not nearly so valuable as if its surface cells had been removed.

The revascularization and replacement of the graft are processes which are well known. Within a few days after the operation the capillaries are growing into the open Haversian canals, and masses of osteoclasts are making excavations in the dead bone. A few days later they are plastering the walls of the excavations with layers of new bone. As the blood vessels

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Melbourne, 1931.

the interior of the bone, osteoblasts move in also, o carry on the processes of absorption and replace- from within at the same time that they are going the surfaces In this way the graft is ultimately absorbed and replaced with new cancellous bone, may be expected to overcome the defect for which peration was performed. If this defect has been a nion in a fracture, the success of the operation will d on several factors These are first, healing by y union, secondly, the firm healing of the graft e fragments, thirdly, the firm healing of the frag- to one another, either through the graft alone or gh new bone joining the fragments to one another d the graft

question of the firm healing of the graft to the ents is of great importance in a review of the failures after time cases have come into hospital with per g non union because the graft has failed to unite e of the fragments An analysis of these cases shows one or more defects in the operative technique nt for the failure The commonest defect is neglect sure contact of graft to bed over a sufficient area utile to expect to overcome non-union by introducing ft which only butts against a freshened fragment sts in a bed half an inch long, as is so often the In a radius or ulna the graft should be embedded ast an inch and a half into each fragment, and in a at least two and a half inches Another defect is e to secure close apposition of graft to fragments has referred to this over and over again in his s, and he is perfectly right in the matter I have dozens of failures result from one end of a graft contact with its bed, or from the careless fitting aft and bed, so that contact occurs only at points, not throughout surfaces Study of the union of bone blants to their beds in experiments on dogs is most ncing in this regard If the graft is placed in tight ct with its bed, union takes place within two weeks ne laying down of trabeculae of new bone on the es and without the intermediate stage of cartilage rous tissue formation If even a narrow space is left en the graft and its bed, union is much delayed, if the space is as much as an eighth of an inch, may evented altogether Clinical experience confirms thes- imental observations completely, and demonstrates the successful grafting of bone calls for a fair degree ftsmanship

seems hardly necessary to speak of immobilization portant in securing success in bone transplantation ten do operations fail, however, because of neglect mobilize, that a word here may be of value I am nced that immobilization is of even greater impor in a bone grafting operation than in a simple ure, and to secure it we should not only use an nal splint in the form of plaster, but we should use form of internal fixation which will ensure perfect in the healing area until consolidation of the callus ccurred

fourth point of importance concerns the bed into the graft is to be laid In most cases in which ne graft is necessary the ends of the fragments have ne so sclerosed that they are almost totally incapable acting to irritation Such bones are hard like ivory, very little when cut, and show practically no cellular ity when injured It is well known that op rations g at overcoming non union in this kind of bone, simply provide for bringing freshened ends into act, almost always fail For the same reason bone s fail to heal to this kind of bone, and experienced tors know that, to have any chance of success, the must extend beyond the sclerosed area and come in act with healthy bone. A preferable technique, which will be discussed later, gets rid of most of the sclerosed bone and replaces it with an appropriately shaped graft

Some writers have been so impressed with the importance of cutting through the sclerosed bone at the ends of the fragments that they have inclined to the idea that this is the really important part of the operation, and that, except in so far as the bone grafting operation requires the free opening up of the fragments, it is not a real contribution to the treatment of non union Waring and Milligan in 1922 published a paper in which they suggested that the delib rate comminution and artificial impaction of the fragments was a more dependable method of treatment than bone grafting They cite cases in which bone grafting had failed, and the communion operation had subsequently proved successful In this, however, they are undoubtedly mistaken, although the point they emphasized is of basic importance in inducing union Without the thorough opening up of the fragments bone grafting would be futile With the fragments well opened, however, it has been our experience that a bone graft operation well done greatly increases the probability of solid union, and is a most valuable addition to our treatment

A good deal has been said about the stimulus that the bone graft gives to the osteogenetic cells in the ends of the fragments Whether such a stimulus exists or not I have been unable to determine It seems clear, however, that it is of no great importance, as the osteogenetic activity in the ends of fragments in experimental animals seems to be quite as great when the fragments are simply cut open as for the reception of a graft as when the graft has actually been inserted

Technique of a Bone Graft Operation

The technique of a bone graft operation must necessarily vary a great deal, depending on the problem presented It is folly to try to force the same plan on all cases As a rule, the surgeon must determine the mechanical details of his operation after the field has been exposed The operation will be considered under the headings of the preparation of the fragments, the preparation of the graft, and the insertion of the graft

Preparation of the Fragments

To prepare the fragments properly an adequate incision is required, a longer one than is needed for a plating operation, as the motor saw must be used in the wound. The fragments are then brought into line, and, if possible, into contact During these manipulations we avoid all unnecessary injury to the circulation of the fragments. The temptation to strip the periosteum freely off the terminal two or three inches of the fragments must be resisted, as this invariably results in extensive aseptic necrosis, which reduces the fragments to more or less the same condition as the graft, and so lessens the tendency to healing I have seen several cases fail to unite, and several others definitely delayed in uniting, in what were otherwise technically good operations because of ruthless stripping of the periosteum

The next step depends on the thickness of the bone involved If it is the radius, ulna, clavicle, fibula, or one of the slender bones of the hand or foot, the motor saw is applied to the fragments so as to cut out a V shaped piece from the end of each, as shown in Fig 1 This V shaped piece of bone takes out practically all of the sclerosed bone which plugs the medullary canal, and opens the fragment well back to the normal medullary cavity An osteotome is then applied at the point of the V, and the shaft split till the two halves stand open widely This is the preparation for the diamond graft described by Albee

In the case of the tibia, femur, and humerus the diamond graft operation is obviously not suitable, and

some form of inlay, or onlay, or medullary plug must be employed. We are altogether in favour of some type of inlay, as it conforms best to the principles which we think should govern bone grafting. The onlay graft deforms the part, it interferes with subsequent function, and it fails to make the most use of the osteogenetic powers of the fragments, as it does not open up the endosteal region. The medullary plug is defective in that it is often difficult to insert it far enough beyond the area of sclerosed bone, and it too often literally acts as a plug and prevents the outflow of osteogenetic tissue from the interior of the fragments. The inlay graft, on the contrary, does not add to the deformity ; it may be made as long and as wide as is necessary, and in cutting the bed for it the fragments are thoroughly opened up, almost as well as in the diamond-graft operation, so that every advantage is taken of the natural powers the fragments may have towards healing. In our experience it is much the best method.

The preparation of the fragments in such large bones as the tibia consists primarily in restoring proper apposition and alignment. This usually calls for some stripping of the periosteum, but it should be kept to a minimum. At the same time the fibrous tissue, cartilage, and bony plates on the ends of the fragments should be removed, and the freshened surfaces brought into as close contact as possible. If there is any tendency for the fragments to slip apart, and particularly if any amount of force is required to keep the ends in close contact, I always use some form of internal fixation, such as a beef bone or steel screw, or even a steel plate and screws. This precaution does away with the risk of the fragments slipping during the application of the splints or afterwards.

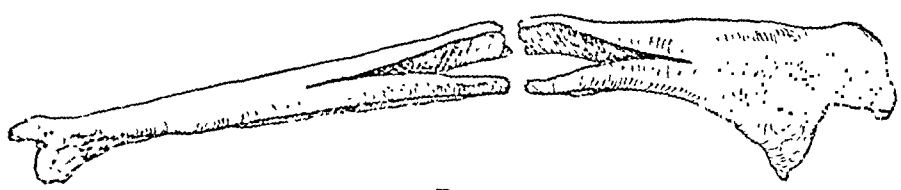

FIG 1.
Bone prepared for diamond-shaped graft.

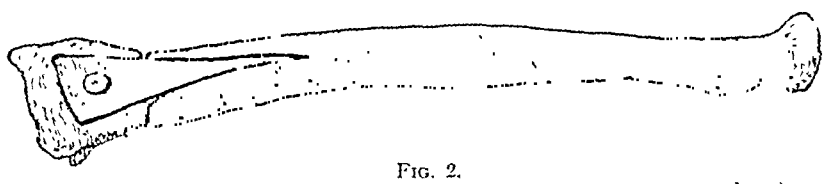

FIG. 2.
Diagram showing method of introducing graft in ununited fracture close to extremity of bone.

The preparation of the bed for the graft is now proceeded with. With a single or twin saw a wide mortice is cut, extending about three inches on each side of the fracture, if this is possible, and exposing the medullary cavity. In the immediate vicinity of the fracture this will still be plugged with sclerosed bone, which must be chiselled out completely. If the fracture is in or close to the expanded end of the bone, length must be sacrificed in the graft, but to make up for this the mortice and graft may be cut much wider there so as to make a dovetail (Fig. 2).

Preparation of the Graft

The preparation of the graft is of the greatest importance. The requirements of a suitable graft may be summarized as follows:

1. It must contain sufficient living elements to enable it to take an active part in the healing of the fracture.
2. It must be strong enough to act as a temporary internal splint.
3. It must be of such a type that it will resist the disintegrating effect of the invading osteoblasts until sufficient new bone has been laid down in and around it to prevent its collapse.

In order that the maximum of living cells may be transplanted with the graft, its periosteal and endosteal surfaces must be preserved. I do not mean by this that the periosteum should be transplanted with the graft, but our experiments, and those of many others, have shown that the amount of new bone forming on the surface is approximately the same, whether the periosteum is transplanted with it or not. As a rule, in cutting the graft we do so subperiosteally and preserve the periosteum to sew over the cavity left by the removal of the bone in order that a subcutaneous haematoma may be prevented. *In removing the graft, however, the periosteal* surface should not be roughly scraped or chiselled, as such treatment would undoubtedly remove the osteoblasts which are lying in all the irregularities of its surface. Similarly, the cancellous bone which lines the deep surface of a tibial graft should be preserved, as it is readily permeated by lymph, and contains large numbers of osteoblasts which quickly spring into activity after the transplantation, and are very important in absorbing and rebuilding bone.

The choice of the particular bone that shall be used in any given case is always important. Our experiments have shown that the transplantation of loose-textured bone, such as rib or crest of ilium, is followed by much more active proliferation of osteoblasts and much more rapid absorption and replacement when the transplant is cut from the hard, compact bone of the crest of the ilium. Theoretically, therefore, cancellous bone should be preferable for transplantation. This is not so, however, in all cases, for in fractures of long bones, such as the tibia, if a transplant of cancellous bone is used, it rarefies so quickly that a fracture often occurs through it, which usually fails to unite again. For long bones, therefore, particularly those in which union naturally takes place slowly, sufficient compact bone is required in the graft to enable it to act as an efficient splint and a trustworthy bridge until new bone formation is well established. The bone that best supplies these requirements is the inner face of the tibia.

One sometimes has to decide whether the graft should be taken from the fractured bone itself, making a so-called "sliding graft," or whether it would be better to go to the opposite limb. As a rule, the sliding graft is perfectly satisfactory, and is therefore preferable. Occasionally, however, when the ends of the fragments are very sclerosed and it is certain that union will be delayed in any circumstances, and where the bone is thin for a distance beyond the sclerosed ends of the fragments, or very thin and atrophic, it is better to cut the graft from a normal bone, and so avoid the risk of failure. The trouble with the sliding graft in the tibia is that it tends to absorb and disintegrate before new bone has formed, very much like grafts of ribs and iliac crests.

There is a distinct place, however, for cancellous bone as transplants. Nothing has been so satisfactory in our hands as rib for non-union in the mandible, for operations designed to fuse joints such as the astragaloid, or to fuse the laminae of the spine together, I like to lay in the prepared bed between

ical bone and a crushed-up mass of cancellous bone, he idea that a great proliferating mass of bone-g cells will result and ultimately fuse all the raw surfaces together. Experimentally it can easily be strated, by transplanting a block of cancellous bone ne muscles of an animal's back and in another place lanting a similar block after it has been well crushed at after three or four weeks a great deal more new formation takes place around the crushed bone round the solid piece. The explanation is that more bone surface has been exposed, and therefore more cells brought into contact with lymph. Clinic-ne same thing can be demonstrated by examining of patients in whom fusion of the vertebrae has ttempted with a single graft in one case and by le strips and crushed grafts in another.

Cutting and Insertion of Graft

technique of cutting and inserting the diamond s worth reviewing. With the fragments prepared ready de-l, the sur- exposes a reflects the eum, and the motor cuts a id-shaped which is as t its central is the trans- diameter of ne, such as radius or into which to be in-. It tapers to a fine at each end, from three ree and a nches long. aw cuts are perpen-r to the periosteal surface, and they go right gh to the medullary cavity, so that the graft is on its deep side with cancellous tissue This graft n held by a suitable forceps, and one end of it mered into the split fragment which has been pre- for it (Fig. 3). The other fragment is then sprung by means of a narrow osteotome, and the other end graft pushed into its bed If this graft has been fit the bed it will now be held firmly in the split f the fragments, and may require no further fixation rule, however, it is not safe to omit further fixation, graft has been known to pop out at one end at stage in the manipulations, and so spoil the whole tion. It has been our custom to pass a drill trans-y through each fragment as it embraces one end graft, and to slip a beef bone pin through this hole. is way accidents are avoided (Fig. 4).

insertion and securing of the inlay graft also es care. As mentioned above, if there is a strong ncy for the fragments to slip sideways, we do not te to immobilize them with steel screws or plates. ot absolutely necessary, however, we omit non-bable material We make a point of seeing that the fits its mortice accurately and has contact over a area. We further make sure that graft and mortice ressed tightly together, and this is done by fastening raft down in its bed in each fragment by one or more beef-bone screws, or, if greater security is needed, by long steel screws The main point is to get a strong graft which is well lined with cancellous bone solidly embedded in the fragments and to fasten it there, so that there is no risk of a little accident spoiling what has often been a serious and difficult operation.

The use of boiled beef bone in the form of pins and screws has been very helpful in immobilizing both fragments and grafts. The screws are inserted into holes which have been drilled and tapped with a special cutting tap. Being ordinary beef bone they have ordinary Haversian canals into which new blood vessels quickly grow, and they undergo the changes which occur in an ordinary autogenous graft—namely, absorption and replacement. The only difference that one can detect between the changes occurring in the boiled beef bone and in the autogenous is that in the former all changes are much slower. It takes six months for a bone screw to be replaced by living bone, whereas an autogenous graft of similar size would have lost its identity in half the time.

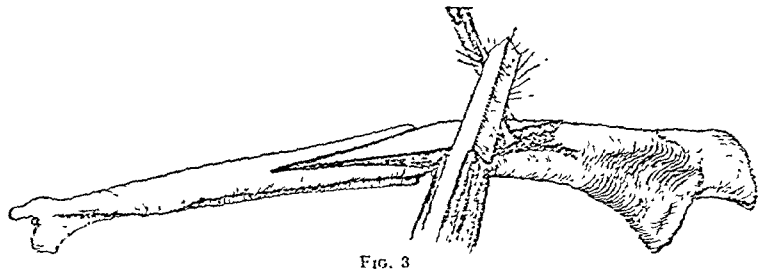

FIG. 3

Graft being hammered into position.

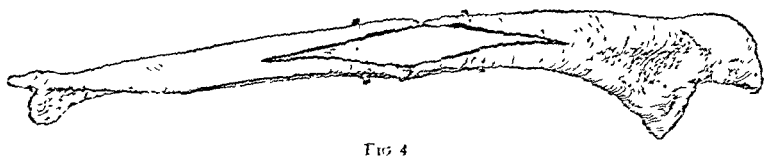

FIG 4

Graft fastened in position with bone pegs

BRIDGING GAPS

The great frequency of failure in attempts to bridge gaps in the long bones by means of transplants has led to almost complete abandoning of the method Experience has shown that it is usually wiser to accept shortening sufficient to bring the ends of the fragments into contact or nearly so and then do a bone graft, than to attempt to maintain the length and to bridge the gap by any method of bone grafting yet devised As a rule, such attempts have ended in failure owing to fracture of the graft. A study of such grafts in animals has shown that these fractures occur close to the point of contact of the graft with its bed, and are due to the fact that absorption has been going on in the graft more rapidly than the building up of new bone, so that a time comes, between two and three months after the operation, when the graft, which originally was quite strong, has softened down till it cannot stand any strain, and so spontaneously fractures.

Occasionally, however, it is absolutely necessary that a gap be bridged, as, for example, in ununited fracture of the mandible. In such cases the surgeon should bring to his assistance all the forces he can command Thus, in addition to bringing a suitably shaped graft into intimate contact with the bed in the fragments, provision must be made to ensure that the greatest number of osteoblasts possible survive and take part in rebuilding the graft. This requirement has been met by using a rib which has been split on the flat so as to allow lymph to bathe the cancellous bone of the interior This plan, if combined with rather prolonged immobilization and a guarded return to motion, will cure most cases of non-union of the mandible

In the rare cases of fracture in the long bones in which it is necessary to bridge gaps, as in severe loss of substance

in the ulna or radius, one must combine the diamond type of graft with multiple slivers, strips, and crushed up cancellous bone, which is laid in the periosteal tube along with the diamond graft. The latter forms a framework upon which the smaller grafts can build new bone and so ultimately fill the space with material strong enough to do the work of the normal ulna or radius.

Conclusion

Much of what I have said has had to do with failures. Failure, however, should occupy a very unimportant place in the surgery of bone grafting, and if the general principles discussed are remembered when the operations are being performed, it will be rare that a failure will need to be recorded.

ABDOMINAL MANIFESTATIONS IN RHEUMATISM

BY

K. H. TALLERMAN, *M.C.*, M.D., M.R.C.P.

ASSISTANT PHYSICIAN TO THE CHILDREN'S DEPARTMENT, THE LONDON HOSPITAL; PHYSICIAN TO PADDINGTON GREEN CHILDREN'S HOSPITAL

Although abdominal manifestations in rheumatism are quite well recognized and have frequently been reported, cases in which pain in the abdomen is diagnosed at the outset as definitely rheumatic in origin must be very rare. It is usual for the rheumatic nature of such symptoms to become apparent a few days after their onset, and thus make the diagnosis certain. In a recent paper Giraldi[1] has called attention to this subject, and has given a very good review of the literature relating to it. The matter seems to be of sufficient importance to merit a report of the following cases, and prompts one to consider how frequently abdominal pain in childhood, in the absence of other symptoms, may be rheumatic in origin.

Case I

D. H., male, aged 10 years, was admitted on the surgical side of the London Hospital, under the care of Mr. Alan Perry. Family history was negative. Past history: The boy was said to have suffered from rheumatism, with involvement of the heart, at the age of 5; since then he had suffered from time to time from limb and joint pains, which had sometimes been severe. No history of repeated sore throats or colds. Present illness: Four days before admission he complained of pain in the lower abdomen, and vomited; bowels had been constipated for two days.

December 8th, 1930 (on admission): There was tenderness and rigidity in the right iliac fossa, and appendicitis was diagnosed. At operation the peritoneal cavity was found to contain a little clear fluid, and the appendix was injected. On section it was reported to show changes consistent with slight chronic appendicitis, which, however, did not appear to be due to an acute attack. The boy progressed well for seven days, and then the temperature began to rise again.

December 16th: The boy looked ill, but, except for slightly diminished air entry and impaired percussion note over the lower lobe of left lung, no abnormal signs were noted. The following day a friction rub appeared in the precordial area, which subsequently became more marked and was heard distinctly all over the precordium.

December 30th: The patient was extremely pale. No rheumatic nodules noted. Throat normal. Heart: signs of pericardial effusion; mitral systolic and soft diastolic murmurs, and accentuated pulmonary second sound. Lungs: in left lower lobe percussion note impaired, with tubular breath sounds and crepitations, but nothing further abnormal. Liver enlarged almost down to umbilicus. The operation wound was healed.

January 2nd, 1931: Pericardial effusion markedly decreased.

January 12th: Hardly any effusion noted; lungs practically clear.

February 6th: Much better. Area of cardiac d[ullness] normal; at apex, systolic murmur still heard and s[econd] sound reduplicated; pulmonary second sound accentuated.

March 2nd: No reduplication of apical second sound [now] present, otherwise physical signs in heart unchanged.

March 3rd: Some pain in left shoulder, and rise of temperature and pulse rate.

March 7th: Patient seemed very well. Pulse rate 8[0] to 90. Condition of heart as above; apex beat not fixed; no other signs of adherent pericardium. Liver not enlarged.

About a week later the boy was discharged to a convalescent home. He was treated with sodium salicylate [only] in hospital.

Case II

S. H., female, aged 8. Family history was negative. P[ast] history: The girl was said to have had rheumatic fever, [but] the exact age at which this occurred was not [known]. Generally speaking she had not suffered from limb or joint pains, and there was no history of frequent sore throats or colds. She was admitted on the surgical side of the [London] Hospital (May 2nd, 1929) under Mr. Lett, with a history of vomiting and pain in the right iliac fossa for three days, and one day pain in the right knee. She appeared flushed and [ill], had a furred tongue, and there was tenderness and rigidity on the right side of the abdomen. The heart at this time appeared normal. Appendicitis was diagnosed. Operation revealed an oedematous and injected appendix containing threadworms. On section the appendix was reported to show the changes of slight acute appendicitis, sufficient to have accounted for her symptoms. Three days after operation pain in the right knee was more marked, and the left knee was also painful.

May 7th: Acute rheumatism diagnosed.

May 13th: Blowing mitral systolic murmur noted for the first time. Patient transferred to the children's department.

May 15th: Knees tender but not swollen. No rash noted. Heart not enlarged; localized blowing mitral systolic murmur; pulmonary second sound accentuated; no other abnormal physical signs. Pulse somewhat rapid, but otherwise child progressing well.

July 3rd: Physical signs in heart unchanged, except that the systolic murmur was not quite so marked.

July 31st: Child now appeared very well; no abnormal physical signs, and pulse rate had decreased.

August 23rd: Tonsillectomy performed.

September 17th: Child discharged. Heart apparently normal at this time; pulse rate 88 to 90.

The patient was treated with sodium salicylate during the early part of the illness.

I should like further to mention a case which I had the opportunity of seeing while working with Dr. Marriott at the Children's Hospital, St. Louis, U.S.A. The child was admitted to the hospital on account of abdominal pain, and on examination appeared to present a picture of acute appendicitis. The case was not, however, entirely typical, and the surgeon who saw the child decided to wait and watch him for a period. On the following day he had pain and swelling of the joints, and a typical attack of acute rheumatism developed, and ran a normal course.

Discussion

It is still open to question whether appendicitis may be caused by acute rheumatism, or whether acute rheumatism itself may cause symptoms resembling those of acute appendicitis. I feel that the above cases support the fact that abdominal disease may be a manifestation of rheumatism. The pathological changes in the appendix were slight in both of the cases reported, but there can be no doubt that these children were suffering from rheumatism. (The appendix showing the principal pathological change was that found to contain threadworms.) These cases are similar to certain of those already discussed by Giraldi and others.

i view of the frequency with which rheumatism occurs hildren of the hospital class, and the number of times is confronted with a child suffering from abdominal witho other signs or symptoms, it is worth while idering how often children with these abdominal sym-ns may be actually suffering from rheumatism, of h this pain is at the time the only manifestation. his connexion the "digestive group" of rheumatic ents dis ss d by Giraldi[1] is significant. Another point nterest is the relationship which exists in childhood een sore throat, appendicitis, and abdominal pain, first of which often appears to precede either of the rs; this has been fully discussed by Brennemann,[2 3] seems to be of importance here because of the known ciation of tonsillitis with rheumatism Obviously the ibility of a case that presents the features of true endicitis proving to be rheumatic in nature must not held to contraindicate operation, since, if the case uld actually be one of rheumatism, no great harm uld result, whereas a tragedy is likely to occur if acute endicitis is left without surgical intervention.

ases such as the above probably occur more frequently n is generally realized, and on this account it seems sable that attention should be directed to them.

should like to thank Dr Bratton for the pathological rts and those members of the staff who had care of patients, for permission to report these cases

YCHIA AS AN OCCUPATIONAL DISEASE*

BY

H. HALDIN-DAVIS, M D, F R C P.

DERMATOLOGIST TO THE ROYAL FREE HOSPITAL

sidering how much the nails are exposed to inflamma- and injury in innumerable industrial processes, it is arkable how little has been written about them in the literature that has grown up in the last twenty years ing with occupational diseases of the skin and its endages. In the latest edition of Prosser White's on occupational diseases of the skin there is scarcely mention of the nails In the exhaustive treatise on same subject emanating from the Viennese school, ected by Oppenheim, Rille, and Ullmann, there is a t chapter on the subject contributed by Heller of lin, who for the last thirty years has been studying ases of the nails, and is undoubtedly the greatest ority on them at the present time Heller's chapter lustrated by many excellent photographs, and shows ny instances of deformity and atrophy of the nail ught about by various industrial occupations Very arkable are the erosions of the nails which occur ong those who work in calcium chloride. Apparently, ll collections of this substance are caught under the margin of the nail and act almost like cauterizing nts on the tissues in the vicinity. Alterations in the s owing to concomitant eczema are also well known, occur in many departments of chemical industries. other interesting industrial disease of the nail is that ch affects certain workers in breweries. Those work-n whose duty it is to clean out the casks in which mentation takes place often remove adherent masses yeast with their finger-nails, and this causes the nails be riddled with lacunae, while crusted excrescences w beneath and cause the destruction of the nail t, however, of the lesions here described deal with alterations of the terminal portion of the nail, which frequently in many industrial occupations becomes rubbed down by friction or softened by the macerating action of various fluids It is well known, for example, that washerwomen never have to cut their nails, which are always soft and occasionally become loosened

The type of lesion to which I wish particularly to direct attention does not, however, figure at all conspicuously among the recorded injuries inflicted on the nails by industrial conditions I refer to chronic onychia In the exhaustive treatise of Oppenheim, Rille, and Ullmann the word does not appear in the index I have also searched the literature for some reference to onychia as an industrial disease, but can find no paper bearing on this aspect of the complaint The only variety of onychia which has stirred clinicians to publication appears to be syphilitic onychia, which is the subject of several papers, and I now learn from Dr Rolleston that diphtheritic onychia has been described

The clinical characteristics of chronic onychia hardly require recapitulation The skin at the base of the nail is thickened into a dull red sausage-shaped roll, encircling the nail and gradually tapering off as it approaches the distal end. There is no great quantity of pus produced, but an occasional bead of moisture may be expressed In cases which have continued for some months, the nail-plate itself gradually loses its smooth and polished surface, becomes wrinkled, and may be actually deformed I have seen a case in which the formation of the nail-plate was so seriously interfered with that only heaped up friable material was formed, which really hardly bore the slightest resemblance to normal nail substance There is a certain amount of tenderness at the inflamed bases of the affected nails, but otherwise the symptoms are not severe

In my opinion, most cases of chronic onychia are caused by occupations which necessitate frequent immersion of the fingers in water, and the incidence of the complaint is probably encouraged when soda is used freely Such occupations are beer bottling, office-cleaning, and that occupation which, notwithstanding the social stigma supposed to be attached to it, is still the most widely followed in the world—namely, domestic service The influence of continual moisture was well exemplified in the case of one young patient, a girl, employed in beer-bottling She used to grasp the neck of the bottles with the left hand, and the beer continually overflowed on to her fingers, she contracted onychia on that hand only, while the fingers of the right hand, which were only seldom wetted, escaped. Another patient was a lady who, during the war, volunteered to do the washing for several of her soldier relations returning on leave. She contracted chronic onychia, which took several years to clear up. I think that it is commoner in women who only become exposed to this danger comparatively late in life than in those who are brought up to what may be described as the "rough work" of domestic service Moreover, in many cases the hardened charwoman regards a slight amount of onychia as normal or "all in the day's work" I think that if one takes the trouble to examine the fingers of many of these ladies one will often find a slight degree of thickening of the skin round the base of the nail, even although they make no complaint about it Another cause of onychia occasionally seen but which is hardly describable as an occupational disease is manicuring There are some women who contract the condition from using the orange stick with excessive vigour It may be of medico-legal importance to bear this possibility in mind Circumstances may easily arise in which the occupation of the patient may be blamed for that which is really the result of a pardonable vanity, and the tendency of legislation is continually putting additional

*Paper read in the Section of Dermatology at the Annual Meeting of the British Medical Association, Eastbourne, 1931

temptations in the way of patients to ascribe all their misfortunes to their employments.

One reason, perhaps, why onychia has not drawn much attention as an occupational disease may be that many of the cases occur in patients whose hands are already affected by severe industrial dermatitis, and in whom it is largely secondary to that dermatitis. Here I am especially concerned with onychia occurring independently, and I think that if looked for it will be found to be of more importance industrially than has hitherto been supposed.

A NEW METHOD FOR THE INJECTION OF LIPIODOL

BY

ERNEST FLETCHER, M.A., M.B.CAMB.,
M.R.C.P.LOND.

ASSISTANT PHYSICIAN, QUEEN MARY'S HOSPITAL, STRATFORD; PHYSICIAN, ST. MARYLEBONE DISPENSARY; REGISTRAR ROYAL CHEST HOSPITAL

The intra-bronchial injection of an iodized oil, opaque to the *x* rays, for the diagnosis of certain conditions of the lungs and bronchial tubes has been practised for some time. This method of investigation has advantages peculiar to itself, and there is no other method which gives the same information. It is therefore important that the method of injection should be rapid, painless, and efficient. The condition under treatment may require repeated injections of the oil, and the objections of patients to these repeated injections by the methods at present in use has made it apparent that some easier and more rapid technique should be evolved.

There are two possible methods of injection: the intra-laryngeal (usually called the oral route), and injection through the crico-thyroid membrane direct into the larynx.

The great disadvantage of the oral route is that it is *not applicable to children. The condition which most* commo- Family ires lipiodol injection, a pneumonitis in- volv- said to hav- bronchi, occurs frequently in children, so the heart, at the ot to evolve a technique of injection which to time from lim- lly *applicable only the alternative* m- present illness: Four da- ed.

January 12th: Hardly any effusion no constantly apart and clear. To the end of the it. A filling tube is l needle with lateral holes fits the syringe. On this needle a shoulder may be placed, if desired, to prevent it penetrating the larynx beyond a certain point.

TECHNIQUE OF INJECTION

The injection may be made through the crico-thyroid membrane or between two of the upper rings of the trachea. Some time before the injection the skin over the selected site is swabbed with spirit and painted with 1 per cent. picric acid, and this area protected with sterile cotton-wool held in place by a bandage. Before proceeding with the injection the patient should be instructed to bring up as much sputum as possible. At the time of injection the dressing is removed, the patient lies down and, using a syringe fitted with a very fine hypodermic needle, the skin is anaesthetized with 1/2 c.cm. of 2 per cent. novocain and adrenaline. It is good practice to form a bleb to mark the position of the crico-thyroid membrane. The filling tube is fitted to the special syringe and the lever is compressed until the piston reaches the end of the barrel. The tube is then placed in a bottle of warmed oil and the pressure gradually released. As the spring separates the arms of the lever, the piston moves and the oil flows into the barrel.

The piston is so arranged that it goes past the 20 c.cm. mark; the barrel therefore contains 20 c.cm. of oil and 3 to 5 c.cm. of air. The filling tube is removed and the needle attached. The syringe is then inverted and the air expelled. The piston is kept steady at this point by means of a check-piece. The filling of the syringe and fitting of the needle takes about thirty seconds.

Special syringe, showing filling tube (above), and needle with shoulder fitted.

With adults it is now usual to inject about 5 minims of 10 per cent. cocaine hydrochloride into the larynx from an ordinary 1 c.cm. syringe, but with children I generally omit this in order to make the operation more rapid.

The needle of the special syringe is now gently pushed through the crico-thyroid membrane until it is felt to enter the larynx, and the patient is sat up. The lever is held firmly and the check-piece re- with the first finger of the right hand. Tension on lever is now gradually released. If the end of the needle in the larynx bubbles of air will enter the syringe. W- this occurs proceed with the injection. At any st- the injection the position of the end of the needle verified by gently releasing the lever. At the end of injection the lever is released, any oil in the needle pulled back into the barrel. The needle is then drawn, the neck gently rubbed, and the puncture

The *x*-ray picture is taken in the upright posture.

There are no after-effects to these injections and complications have occurred.

In practice this method will be found consi- quicker and far more comfortable for the pa- those previously in use. It is not usually ne- admit patients into hospital; provided the c- which the investigation is made permits, the p- may be allowed to go after the investigation is completed.

A syringe of this type, with the various m- they have been introduced, has been in u- months and has given satisfaction. It is made by Allen and Hanburys.

A SIMPLE TECHNIQUE FOR INTRODUCING LIPIODOL INTO THE LUNGS

BY

PHILIP FRANKLIN, F.R.C.S.,

LARYNGOLOGIST, MARGARET STREET HOSPITAL FOR CONSUMPTION, ITALIAN HOSPITAL, ETC.,

AND

ALEXANDER ORLEY, M.D., D.M.R.E.CANTAB.,

ASSISTANT RADIOLOGIST, FRENCH HOSPITAL, LONDON

Several methods have been described for the injection of lipiodol into the lungs. One of the earlier methods was by injection into the trachea through the crico-thyroid membrane. This method is not free from complications, and owing to easier means of access is gradually being abandoned.

The peroral methods may be divided into two groups:

1. The aspiration of lipiodol after cocainization of the laryngo-pharynx.
2. The peroral introduction of a catheter through the anaesthetized larynx.

The disadvantage of the first method is the inevitable partial swallowing of the oil and the difficulty of a uniform distribution of the oil throughout the bronchial tree. The second method as usually performed requires profound anaesthesia of the laryngo-pharynx and expert laryngological skill.

The method we originally adopted at the bronchoscopic clinic at the Margaret Street Hospital for Consumption was that of Dr. Garcia Vicente, which consists of a catheter introduction through the larynx by means of a special forceps for holding and directing the catheter into the larynx. The necessity for profound anaesthesia of the laryngo-pharynx, and the bulkiness of the forceps, which made it especially difficult to use in nervous and young patients, was the reason for our originating this simple technique.

Reasoning that the natural way to the larynx is through the nose, we tried introducing the catheter along the floor of the nose, and were astonished at the ease and simplicity with which the catheter entered the larynx. The procedure is so simple that no previous experience is necessary.

PROCEDURE

The equipment required is: one gum elastic catheter, No. 6 or 7, a 40 c.cm. syringe, and a spray containing a 4 per cent. solution of cocaine.

The patient is seated and the neck slightly extended. One nostril, the oro-pharynx, and the larynx are slightly sprayed with the cocaine solution. The sterilized catheter is gently passed along the floor of the nose until it reaches the posterior pharyngeal wall, when, with a slightly increased pressure, it passes without any difficulty directly into the larynx, because the deglutition reflex has been inhibited by cocainizing the oro-pharynx.

The presence of the catheter in the trachea is proved by listening to the inspired and expired air passing through. Two c.cm. of the cocaine solution are immediately introduced through the catheter. The patient is now ready for the introduction of the oil. The entire procedure should not take longer than three minutes.

The patient is placed on the *x*-ray table, which is tilted into the Trendelenburg position. The injection of the oil is begun. In this position the oil readily flows into the upper lobe bronchi. To ensure an equal distribution in both lobes, the patient is directed to turn first on to the right side and then on to the left. The oil flow is watched on the *x*-ray screen. When indicated a radiogram is taken. This should be done as soon as the bronchial tree appears filled, and before the oil has spread to the alveoli. The table is now put into the horizontal position and the injection of the oil is continued. As before, the patient is directed to turn first on to the right side and then on to the left side. In all, about 40 c.cm of lipiodol are introduced. The filling of the lower lobes is again observed on the *x*-ray screen, and a radiogram is taken when the whole bronchial tree is clearly visualized.

Thirty cases have been done with this technique, and in no case has the result been obtained other than with extreme ease and satisfaction.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

AN UNUSUAL COMPLICATION OF BLOOD TRANSFUSION

The transmission of an acute infective fever from one person to another by transfused blood must be a very rare event. That it can occur is clearly demonstrated by the following case:

The patient was a man, aged 36, who had suffered from pernicious anaemia for many years. He had experienced several previous transfusions of blood, with no subsequent reaction beyond slight pyrexia.

On this occasion he was given 520 c.cm. of defibrinated blood from a private donor at 6 p.m. on February 16th, 1931. The donor and recipient both belonged to Group II (Moss), the donor did not enter the patient's room. The operation was completed without difficulty; the temperature rose during the night to 100.8° F., but no other evidence of reaction was observed.

He remained perfectly well until 4 p.m. on February 18th, when a slight rigor occurred and the temperature rose to 104.2°. Headache was severe; alarming pains came in paroxysms in the back and limbs, at times with such sudden intensity that the patient shrieked in his agony. Extreme tenderness was manifested over musculo-tendinous structures, aponeuroses, and the fibrous parts of large joints, but there was no joint swelling. The tongue was coated, the throat dry and a little red and sore. Salicylates and S.U.P. 36 brought considerable relief. During the night a burning painful cough developed, of the tracheal and high bronchial type.

It appeared to be an attack of severe influenza, which slowly subsided in about ten days, leaving a state of extreme prostration and a very troublesome tracheal cough. No gastro-intestinal features appeared at any time. It was not until three weeks after the transfusion that there occurred to the writer the possibility of infection from the donor. On communicating with him it was found that he had had influenza and was still too ill to leave his house. It appeared that he had been "not quite himself" on the day of the transfusion. Twenty-four hours later, on the following evening, he had been completely overcome by a severe attack of influenza similar to that experienced by the recipient. The pains in the limbs had been less intense, no gastro-intestinal symptoms had appeared, and the attack had slowly passed off in about ten days, leaving him very weak, with a dry cough that was "tearing his chest to pieces."

COMMENT

There can be no doubt that the donor's blood contained active infective matter. The course and features of the attack in each case were almost identical. The greater intensity of the recipient's limb pains may be explained partly or entirely by the fact that he was already suffering from pernicious anaemia, a disease in which bone pains and neuralgia are not uncommon.

The donor's attack preceded the recipient's by twenty-two hours, a point of considerable interest; but it would be unwise to draw important conclusions from it without more precise knowledge of the nature of the infective matter and its time

British Medical Association

CLINICAL AND SCIENTIFIC PROCEEDINGS

CALCUTTA BRANCH

Radiology in Medical Diagnosis

A clinical meeting of the Calcutta Branch was held on September 11th in the lecture theatre of the Calcutta School of Tropical Medicine, when Dr. Kedarnath Das, president of the Branch, was in the chair.

Dr. U. P. Basu read an instructive paper on the value of radiology in medical diagnosis. After a few brief remarks on the history of *x*-ray diagnosis, he described four cases in which the most exhaustive bedside examinations had failed to elicit the precise diagnosis, and in which radiology had had to be appealed to for a solution of the difficulties. The first case was one of obscure chest symptoms in which the diagnosis (a new growth of bronchogenic origin) was finally cleared up by the use of lipiodol and a bronchogram. The second case was that of a young Hindu male student who was admitted to the lecturer's wards complaining of irregular attacks of pain in the right lumbar region, with fever. Dysuria was present during the attacks, succeeded by polyuria of a few days' duration. The right kidney was palpable during the attacks. A pyelogram taken after intravenous injection of uroselectan revealed urethral obstruction, with hydronephrosis. In the third case (a Mussulman seaman) there was a history of intermittent haematemesis and irregular febrile attacks. Clinically the case appeared to be one of aneurysm of the descending limb of the arch of the aorta, but practically all the classical signs of aneurysm in this region were absent. The clinical diagnosis was confirmed by an *x*-ray film of the chest. Dr. Basu's last case was in some respects the most interesting of the series. The patient, a middle-aged Armenian woman, was admitted to hospital complaining of irregular attacks of fever, headache, and generalized body pains, and a tickling throat cough of three days' duration. A radiogram revealed opacity of the right lung, extending from the second to the seventh rib. The condition appeared to be cystic, and a provisional diagnosis of hydatid cyst was made. This was confirmed subsequently at operation, when a hydatid cyst the size of a foetal head was found occupying the right lung. Dr. Basu's cases were retailed with a wealth of clinical observations, and a series of lantern slides rounded off an excellent paper. In concluding, Dr. Basu emphasized the debt of medicine to radiology.

In the discussion that followed, Lieut.-Colonel J. D. Sandes, I.M.S., pointed out that, while medicine undoubtedly owed a debt to radiology, there were also occasions on which radiology owed a debt to medicine. Dr. B. Shaha remarked that he was deeply impressed with the accuracy of Dr. Basu's clinical methods. He urged that bedside methods should always be exhausted before having recourse to radiology. Dr. B. N. C. Roy asked for further information on Dr. Basu's first and second cases. Dr. Basu briefly replied to the various points raised, and expressed thanks to his colleagues on the hospital staff who had assisted in the elucidation of the diagnoses.

Bundle-branch Block

Dr. S. C. Bose followed with a paper on bundle-branch block, illustrated by electrocardiograms. It was a great disappointment to members that Dr. Bose's paper, to the preparation of which he had obviously devoted much care and thought, had to be cut short for want of time. He dealt first with the arterial supply of the two branches of the A-V bundle, pointing out that right branch-bundle block is roughly twenty times as common as left branch-bundle block, owing to the relative arterial poverty of the former branch. The electrocardiograms from a series of ten cases were then shown; eight patients in this series had lesions of the right branch bundle and two had lesions of the left branch bundle. Etiology, age distribution, prognosis, and treatment were next passed in rapid review. In Dr. Bose's opinion branch-bundle block was commoner in Bengal than in Europe, in the proportion of about 1 in 25 cardiac cases from the former country as opposed to 1 in 100 similar cases from the latter country. Syphilis appeared to play a much more important part in the causation of branch-bundle lesions in Bengal than it did in Europe. In the speaker's series of 100 cases seven were of syphilitic origin. The condition could not be diagnosed clinically, and Dr. Bose was frankly pessimistic as to prognosis and treatment.

In the subsequent discussion Colonel Sandes agreed that bundle-branch block was commoner in Bengal than in Europe. Had time permitted, he would have liked to hear Dr. Bose's views on *partial* bundle-branch block. Dr. U. P. Basu said that in his experience bundle-branch block was the result either of infective processes or of muscular degeneration. He asked whether there had been an opportunity for post-mortem examinations in any of Dr. Bose's cases, and, if so, what was the condition of the junctional tissues? Dr. Bose, in reply, said that all his cases had occurred in private, and no necropsies were possible. He pointed out that microscopical examination of the junctional tissues demanded the employment of a very special technique.

Reports of Societies

THE TEACHING AND PRACTICE OF RADIOLOGY

Two new Sections of the Royal Society of Medicine—namely, those of Physical Medicine and of Radiology—have replaced the two old Sections of Balneology and of Electro-Therapeutics. The address from the chair of the Section of Radiology was delivered on October 16th by Professor J. M. Woodburn Morison, who was also the last president of the Section of Electro-Therapeutics.

After relating the circumstances of the new departure, Professor Woodburn Morison spoke on post-graduate instruction in radiology, and made certain suggestions regarding the course of study for the diploma. He believed that the course should extend over three terms—that is to say, a full academic year—and that the subjects comprising the course should be: (*a*) physics and electrotechnics; (*b*) radiodiagnostics; (*c*) radiotherapy, radium therapy, and other forms of treatment by the use of radioactive substances; and (*d*) electrology. The instruction in all subjects should be both theoretical and practical. During the first and second terms all students should be instructed in the four subjects, and during the third term advanced courses of instruction should be given in each subject. Every student should be required to take physics and electrotechnics, and should have the option of selecting any of the other three subjects. Examination should be written, oral, and practical, Part I to be general in all four subjects, and Part II special in the first subject and in the second subject or subjects. This scheme did not contemplate associating electrology from radiology, and he thought the time had not yet come when it was advisable to do so, for he saw no prospect at present of a separate course being instituted in electrology, and, further, there was as yet no diploma in physical medicine for which the subject of electrology more naturally fell. In the scheme he had suggested a general knowledge

subjects would be assured, in addition to specialized knowledge of one or two of them The electrologist would be none the worse for having been taught something about radiology, and some information about electrology could do little harm to the radiologist Physics would be a compulsory subject in both parts of the examination If the student was thoroughly grounded in physics he never regretted it, and invariably, after he had passed the examination, was the first to admit its great practical value

In a later part of his address Professor Woodburn Morison discussed the question of qualification for the practice of radiology Those entitled to practise radiology consisted of all duly qualified and registered medical practitioners who had the requisite knowledge of the subject There was not, and could not be, any logical objection to any consulting physician, surgeon, gynaecologist, or any other qualified medical man doing x ray work, provided he had the requisite knowledge, if he had not got it, and pretended to have it, he was no better than a quack But the speaker wished to stress the necessary corollary Every radiologist should remember that he was first and foremost a physician, but a physician with a specialized knowledge of one branch of medicine He was entitled to treat patients, and, if his knowledge was adequate, to undertake the full management of cases entrusted to him What all practitioners of medicine required, in addition to their knowledge of medicine, was a knowledge of their own limitations and a little common sense The same arguments applied to the teaching of radiology There must be a certain amount of theoretical instruction, but practical instruction was the more important part, and it was there that the personal contact of the student and teacher was of such great value In the course of study for a diploma in radiology it was not essential that the student should have seen and done everything in connexion with the subject it was much better that the teacher should try to give his students, by a thorough study of a few cases, a sound basis on which afterwards they could build "Clinical radiology" was a term for which he offered no apology By use and custom, by its derivation and original meaning, the word "clinical" was applied, not only to bedside teaching, but also to lectures, to wards in hospitals, to the cases in those wards, to medicine and to branches of medicine, and even to the teachers themselves Its extension to radiology was justifiable, but it necessitated that the radiologist, if he was to teach clinical radiology, must have charge of beds Clinical radiology must play a most important part in the teaching of radiology, and that was the province of the qualified radiologist For this he must have charge of beds in the hospital to which he was attached, he must be, in reality, physician in charge of the radiological department, with beds under his control for the study and treatment of cases

THE OBSTETRIC FORCEPS

At a meeting of the Liverpool Medical Institution on October 22nd with Mr FRANK JEANS, vice president, in the chair, Mrs M A DOBBIN CRAWFORD read a paper on the use of the obstetric forceps, which included an account of 100 consecutive cases admitted to the Liverpool Maternity Hospital after failure to deliver by forceps

Mrs Crawford stated that the forceps, applied when the signs were favourable, was an instrument of mercy, used in unsuitable cases, or at an improper time, it was a lethal weapon whereby thousands of living foetuses had been killed, and scores of mothers brought to the door of death To illustrate the frequency of the abuse of that instrument, she had investigated the last 100 cases admitted to the Liverpool Maternity Hospital after attempts to deliver by forceps had failed The reasons for application were in 20 cases, none discoverable (probably a desire to save time or pain), in 64 cases, disproportion, the main factors being post maturity, occipito-posterior position of the vertex, and contracted pelvis The four rules for the application of forceps had been obeyed in only four of the 100 cases In 52 instances forceps were contraindicated, in 44 they had been applied too soon In 59 instances the patient was in the first stage of labour, the smallest degree of dilatation being a two finger os In 40 of these cases severe maternal lacerations were present, the uterus having been ruptured in 3 of them In 36 cases the head was free above the brim, in another 34 the head was entering, the largest diameter being still above the brim The immediate results were that 12 mothers died the morbidity being 31 per cent, and 62 infants died or were stillborn, while 9 of the surviving infants suffered birth injuries No fewer than 20 of the mothers were delivered spontaneously after treatment by sedatives and rest There were several anomalies in the use of forceps (1) it was the most commonly performed operation in general practice, and the one common operation which many students never saw, (2) the excessive force so often applied during the operation was a perfect example of the proverb "Out of sight, out of mind", and (3) the appearance of the scalp during pains did not necessarily indicate that the head was on the perineum, or forceps application had become permissible Having conducted the midwifery of a general practice for seven years, the speaker said she was not ignorant of the difficulties of this most exacting and worst paid branch of medicine She foresaw little prospect of a decrease in the figures of foetal and maternal mortality until public opinion recognized the importance of obstetrics, the unreasonableness of expecting one brain and one pair of hands to do the work of two, and the absurdity of expecting every newly qualified doctor to be an expert obstetrical surgeon The time allowed for practical midwifery in the medical curriculum was far too short, being adequate only for the student who was determined to undertake no obstetrical work after he was qualified

Dr GLYNN WHITTLE said his experience entirely agreed with Mrs Crawford's advice that curved forceps in preference to straight instruments should be used when rigidity threatened He considered that teaching authorities should require improved and extended clinical instruction in midwifery It would doubtless be advantageous to expectant mothers if all doctors commencing practice either devoted themselves seriously to obstetric work or declined midwifery altogether Mr PERCY MALPAS thought Mrs Crawford's paper very significant, particularly with reference to the need for a reconsideration of the diagnosis whenever forceps had failed once The major difficulty in the treatment of these cases in hospital later was that the forceps had been repeatedly applied, so that in addition to trauma and infection, the whole mechanism of the labour was disturbed and subsequent treatment, either active or passive, was often doomed to failure The facts of the whole paper could not be too widely appreciated

Dr S B HERD agreed as to the seriousness of the problem revealed, and the frequency with which a failure to deliver with instruments occurred after a patient had had all her previous children born without help That type of case usually resulted from a condition of post maturity or of weakness of the uterine muscle or of both together Contracted outlet of the pelvis, although uncommon, could result in a failure to deliver with forceps, even when the head had reached the perineum

Carcinoma of the Breast

Mr. Philip Hawe read a paper on carcinoma of the breast, which was based on a series of cases treated at the David Lewis Northern Hospital, Liverpool. After brief reference to the etiological factors, the importance of skin fixation and biopsy in diagnosis of the early case, and the errors that might arise in connexion with axillary tail tumours and traumatic fat necrosis, were considered. The relation of chronic mastitis to carcinoma was discussed, slides being shown to illustrate Cheatle's views on this subject. The great difficulty of distinguishing the so-called "fibro-adenoma" of chronic mastitis from early carcinoma was emphasized, and the same difficulty in connexion with chronic cystic mastitis was illustrated by six cases of malignancy in association with cysts of the breast. The results were divided into two groups. Of 38 early cases, including 9 cases not traced, 29 patients were alive 5 to 10 years after operation; of 74 late cases, including 10 cases not traced, 24 patients were alive 5 to 10 years after operation. Carcinoma in the remaining breast was found in 10 per cent. of the cases surviving operation. One case was quoted in which the patient survived a subsequent pregnancy, but another patient was less fortunate, recurrence being rapid.

In the discussion which followed, Professor R. E. Kelly said that all tumours of the breast must be subjected to microscopical examination. He did not agree that the breast should be removed entirely in all cystic cases. The operation was not complete enough if cancer was found, and it was unnecessary should there be no signs of cancer. Mr. John T. Morrison took exception to the use of the term "fibro-adenoma," as indicating a condition likely to be associated with carcinoma. He limited its application to encapsuled simple neoplasms, rarely, if ever, becoming carcinomatous. In regard to treatment, he stressed the fact that radium was still an experimental method, and its insertion was to be regarded as a major operative procedure. Its value, of course, was great, since even in advanced cases it could be relied upon to produce wonderful local improvement, with corresponding relief of the patient's most distressing symptoms.

At a meeting of the Osler Club, held on October 27th, Mr. W. R. Bett read a paper entitled, "The thyroid: conquests, failures, mysteries, and men." After briefly referring to Vesalius, Eustachius, Morgagni, and Thomas Wharton, he dealt more fully with Gaskell's *Origin of the Vertebrates*. He stressed the very early recognition of goitre in history, linking up Pliny's belief that goitre was caused by impurities in the water supply with McCarrison's classical experiments in India. In sketching the operative story of goitre, an intimate pen portrait was drawn of W. S. Halsted. Mr. Bett concluded his paper with an account of the introduction of iodine into the treatment of goitre and a survey of the present position of exophthalmic goitre; he expressed a hope that the study of the history of medicine might become of real service to medicine by affording it, from an understanding of the past, a peep into the minute ahead. The following took part in the discussion: Sir Walter Fletcher, Mr. T. P. Dunhill, Professor F. R. Fraser, Dr. G. Scott Williamson, Mr. G. L. Keynes, Professor Leonard Findlay, Mr. K. J. Acton Davis, Mr. J. P. Ross, and Dr. J. D. Rolleston.

The new session of the Chelsea Clinical Society opened with the annual dinner on October 20th. At the meeting on November 17th a discussion on the medicinal uses of wines will be opened by Mr. Charles Berry and Dr. G. Murray Levick. Subsequent meetings will be held on the third Tuesday of each month till May 17th, 1932; they will be preceded by dinner at the Hotel Rembrandt, Thurloe Place, S.W., at 7.30 p.m.

SURGICAL PATHOLOGY OF BONE

Professor Hertzler of the University of Kansas is writing a series of monographs on the surgical pathology of various tissues and regions of the body. The first of the series treats of the *Surgical Pathology of the Diseases of Bones*,[1] and the subject is dealt with under two main headings: inflammatory affections together with certain less common diseases of unknown origin, and tumours. The rarer affections are dealt with summarily, the author averring that if a man makes mistakes in connexion with them alone he may consider himself a good surgeon. In both sections the descriptions are pithy and practical, and, especially in regard to the inflammatory affections, will serve the student well as a useful guide in this intricate subject. In the section on tumours the new American system of classification is adopted, and as this differs in some respects from the usual classification it may be worth while to examine it in some detail. The introduction of the terms "osteogenic" and "Ewing's tumour" is that which chiefly characterizes it. Origin is taken as the basis of classification, the site of origin being in some other region of the body, or in one of the constituents of the bone itself—namely, periosteum, osseous tissue, vessels, marrow, or osteoclasts. An additional group is added for certain tumours of unknown nature, and one for tissue formations, which resemble, but are not, strictly speaking, tumours. The following, accordingly, are the headings: (1) metastatic tumours; (2) periosteal fibro-sarcoma; (3) osteogenic tumours, benign and malignant; (4) inflammatory conditions; (5) benign giant-celled tumours; (6) angiomata, benign and malignant; (7) Ewing's tumour; (8) myeloma. Although somewhat lacking in logical symmetry, from the practical point of view this is a useful classification; but a classification based on origin has always been considered to be difficult of application and liable to break down at one point or another. This is likely to occur in connexion with the term "osteogenic," which is defined by Codman, who instituted the Central Registry of Bone Tumours in America, as indicating those tumours "which are believed to be derived from cells which are supposed to be the common ancestors of the cells which form bone, cartilage, the fibrous network of bone, and the tissue formerly called myxomatous." It may be objected that the fibrous elements in bones are not all osteogenic, and that it is impossible to decide what is the origin of a spindle-celled sarcoma, for example. However, objections of this kind may perhaps have little practical weight; in cases of doubt recourse would be had to the ordinary classification, and the tumour would be classed simply as a spindle-celled sarcoma, without reference to its origin. In any case the old classification is needed for the further definition of a tumour, whatever its origin, although Professor Hertzler pours scorn upon it. He will have nothing to do with a classification based on cell-structure, and considers that the old histological classification is not worth discussing. Nevertheless, he proposes to have a similar group of small round-celled sarcomas. As a matter of fact, the old classification is not based on cell-structure but on cell-structure and intercellular character, and includes all the forms embraced in the term "osteogenic" without the necessity of invoking beliefs and supposition. The other feature which especially characterizes the American classification is the "Ewing tumour." Few have had any experience of this growth [illegible]

[1] *Surgical Pathology of the Diseases of Bones, Joints, and Associated Muscles.* By Willis E. Hertzler, M.D. Hertzler's Monographs on Surgical Pathology. London: J. B. Lippincott Company. 1931. (9½ × 6½, pp. 211 figures. 21s. net.)

to express an opinion upon it Hertzler describes it as arising in early life, usually in males, as being of slow onset, accompanied commonly by symptoms simulating inflammation, and as giving a relatively good prognosis when treated with radium, in which respect it differs from the osteogenic sarcomas On these grounds it is placed in a group apart There appears to be some doubt as to the nature of the growth, for, as Hertzler remarks.

"There are said to be twelve men in the world who understand the Einstein theory of relativity I do not believe there are so many who understand this group of tumours The question of the derivation of the tumour cells may be left to the pathologists Ewing believes they are of endothelial origin That should settle it If a mother concludes to name one of her progeny 'Clarence' that is her affair, and it is not proper for alley urchins to rechristen him 'Freckles' Some authors state that these tumours produce no bone and then show pictures illustrating how they do produce bone Some of the cuts published as Ewing's tumours resemble a cross section of a peeved porcupine
